Under the leadership of General Leslie Groves in February 1943, the U.S. military acquired 202,343 hectares of land near Hanford, Washington. This land was one of three primary locations of Project Trinity, which was assigned portions of the duty to produce useful atomic technology. The coordinated activity of these three locations under the auspices of the U.S. military became a path-breaking illustration of the planning and strategy that would define many modern corporations. Hanford used water power to separate plutonium and produce the grade necessary for weapons use. Oak Ridge in Tennessee coordinated the production of uranium. These production facilities then fueled the heart of the undertaking, contained in Los Alamos, New Mexico, under the direction of the U.S. physicist J. Robert Oppenheimer.

In this painting Gary Sheehan envisions the 2 December 1942 scene when scientists at the University of Chicago observed the world's first nuclear reactor (CP-1) as it became self-sustaining. No photographers were present that day. Fifteen years later the artist worked for nearly four months to reconstruct the mood and physical details of this historic event. National Archives.

Oppenheimer supervised the team of nuclear theoreticians who would devise the formulas using atomic reactions within a weapon. Scientists from a variety of fields were involved in this complex theoretical mission. After theories were in place and materials delivered, the project became one of assembling and testing the technology in the form of a bomb. All of this needed to take place on the vast Los Alamos compound under complete secrecy. However, the urgency of war convinced many people that this well-orchestrated, corporate-like enterprise was the best way to save thousands of U.S. lives.

By 1944 World War II had wrought a terrible destruction on the world. The European theater of war would soon close with Germany's surrender. Although Germany's pursuit of atomic weapons technology had fueled the efforts of U.S. scientists, German surrender did not end the U.S. atomic project. The Pacific theater of war remained active, and Japan did not accept offers to surrender. Project Trinity moved forward, using the Japanese cities Hiroshima and Nagasaki as the test laboratories of initial atomic bomb explosions. The U.S. bomber Enola Gay released a uranium bomb on Hiroshima on 6 August 1945, and the U.S. bomber Bock's Car released a plutonium bomb on Nagasaki three days later. Death tolls vary between 150,000 and 300,000, and most were Japanese civilians. The atomic age, and life with the bomb, had begun.

Atomic Futures

Experiments and tests with nuclear and hydrogen bombs continued for nearly twenty years after World

War II. Many of the scientists who worked on the original experiments, however, hoped that the technology could have nonmilitary applications. Oppenheimer eventually felt that the public had changed its attitude toward scientific exploration because of the bomb. "We have made a thing," he said in a 1946 speech, "a most terrible weapon, that has altered abruptly and profoundly the nature of the world... a thing that by all the standards of the world we grew up in is an evil thing."

Many of the scientists involved believed that atomic technology requires controls unlike those of any previous innovation. Shortly after the bombings a movement began to establish a global board of scientists who would administer the technology with no political affiliation. However, wresting control of this new tool for global influence from the U.S. military proved impossible. The U.S. Atomic Energy Commission (AEC), formed in 1946, placed the U.S. military and governmental authority in control of the weapons technology and other uses to which it might be put. With the "nuclear trump card," the United States catapulted to the top of global leadership.

In the 1950s scientists turned their attention to applying nuclear reaction to peaceful purposes, notably power generation. The reaction is a fairly simple process. Similar to power generators fueled by fossil fuel, nuclear plants use the heat of thermal energy to turn turbines that generate electricity. The thermal energy comes from nuclear fission, which is made when a neutron emitted by a uranium nucleus strikes another uranium nucleus, which emits more neutrons and heat as it breaks apart. If the new neutrons strike

other nuclei, chain reactions take place. These chain reactions are the source of nuclear energy, which then heats water to power the turbines.

Soon the AEC seized this sensibility and began plans for “domesticating the atom.” It was quite a leap, though, to make the U.S. public comfortable with the most destructive technology ever known. The AEC and other organizations sponsored a barrage of popular articles concerning a future in which roads were created through the use of atomic bombs, and radiation was employed to cure cancer.

In the media the atomic future included images of atomic-powered agriculture and automobiles. There were optimistic projections of vast amounts of energy being harnessed, without relying on limited natural resources like coal or oil. For many Americans this new technology meant control of everyday life. For the administration of U.S. president Dwight Eisenhower the technology meant expansion of U.S. economic and commercial capabilities.

As the Cold War took shape around nuclear weapons, the Eisenhower administration looked for ways to define a domestic role for nuclear power even as Soviet missiles threatened each American. Project Plowshares grew out of the administration’s effort to turn the destructive weapon into a domestic power producer. The list of possible applications was awesome: laser-cut highways passing through mountains; nuclear-powered greenhouses built by federal funds in the Midwest to enhance crop production; and irradiated soils to simplify weed and pest management. Although domestic power production, with massive federal subsidies, would be the long-term product of government effort, the atom could never fully escape its military capabilities. This was most clear when nuclear power plants experienced accidents.

Accidents Fuel Public Doubt

A number of nuclear power plant accidents occurred before the late 1970s, but they went largely unnoticed by the U.S. public. Nuclear power became increasingly popular, even though critics continued to argue issues of safety. In 1979 the United States experienced

its first nuclear accident in a residential area outside of Harrisburg, Pennsylvania. The accident at Three Mile Island (TMI) nuclear power plant entirely altered the landscape of American power generation. Although involving only a relatively minor release of radioactive gas, this accident demonstrated the public’s lack of knowledge. Panic ripped through the state, and Harrisburg was partially evacuated.

Of course, the international community took notice of the TMI accident; however, it clearly did not present a grave threat to the world. The world’s other superpower had even greater difficulty with its atomic industry, which was plagued by accidents throughout this era. None, however, compared to the Chernobyl meltdown that occurred in Ukraine in 1986. During a test the fuel elements ruptured and resulted in an explosive force of steam that lifted off the cover plate of the reactor, releasing fission products into the atmosphere. A second explosion released burning fuel from the core and created a massive explosion that burned for nine days. It is estimated that the accident released thirty to forty times the radioactivity of the atomic bombs dropped on Hiroshima and Nagasaki. Hundreds of people died in the months after the accident, and hundreds of thousands of Ukrainians and Russians had to abandon entire cities.

The implications of nuclear weapons and nuclear power had already been of great interest to environmental organizations before Chernobyl. After Chernobyl international environmental organizations such as Greenpeace dubbed nuclear power a transborder environmental disaster waiting to happen. Interestingly, even within the environmental movement, nuclear power maintained significant support due to its cleanness. Whereas almost every other method for producing large amounts of electricity creates smoke or other pollution, nuclear power creates only water vapor. Yet, at least in the public’s mind, there remained the possibility of atomic explosions.

Growth in the International Market

Although accidents decreased the U.S. domestic interest in nuclear power generation, the international

All the waste in a year from a nuclear power plant can be stored under a desk.

• Ronald Reagan (1911–2004)

community refused to be so quick to judge the technology. Since the early 1990s nuclear power has become one of the fastest-growing sources of electricity in the world. Nations that depend on nuclear power for at least one-quarter of their electricity include Belgium, Bulgaria, Hungary, Japan, Lithuania, Slovakia, South Korea, Sweden, Switzerland, Slovenia, and Ukraine.

According to the *Bulletin of the Atomic Scientists*, nine countries possessed nuclear weapons capability (United States, China, France, Russia, and Britain, India, Pakistan, Israel, Korea). Thirty nations have some 440 commercial nuclear power reactors. Currently fewer nuclear power plants are being built than were built during the 1970s and 1980s, but the newer plants are much more efficient and capable of producing significantly more power. Additionally, nuclear power is being used for needs other than public electricity. In addition to commercial nuclear power plants, there are more than 280 research reactors operating in fifty-six countries, with more under construction. These reactors have many uses, including research and training and the production of medical and industrial isotopes. Reactors are also used for marine propulsion, particularly in submarines. Over 150 ships of many varieties, including submarines, are propelled by more than two hundred nuclear reactors.

Finally, nuclear power has also become a volatile part of international politics. Nations such as North Korea and Iran have used their pursuit of “peaceful” nuclear technology to raise the ire of many western nations in hopes of forcing them into negotiations. Particularly in the case of Iran, many nations are suspicious of its claims of “peaceful” uses. Fearing their own security, Israel and other nations have demanded that Iran not be allowed to develop new nuclear technology of any sort. These fears seem to have made it more attractive for rogue nations to increase the threat level.

Regardless of the use to which it is put, nuclear energy continues to be plagued by its most nagging side effect: even if the reactor works perfectly for its service lifetime, the nuclear process generates dangerous waste. In fact, reactor wastes from spent fuel rods are believed to remain toxic for fifty thousand

years. At present each nuclear nation makes its own arrangements for the waste. U.S. nuclear utilities now store radioactive waste at more than seventy locations while they await the fate of the effort to construct and open a nuclear waste repository inside Nevada’s Yucca Mountain.

Internationally, the situation is not much clearer. Opponents in Germany have obstructed nuclear waste convoys, and shipments of plutonium-bearing waste to Japan for reprocessing are often placed under dispute. Some observers have voiced concern that less-developed nations will offer themselves as waste dumps for the more-developed nations. The income from such an arrangement may be too much to turn down for many nations.

Rising energy prices of all sorts, however, brought the nuclear industry robust interest in the twenty-first century. In particular, new attention has been focused on reprocessing used nuclear materials. In this fashion, the very idea of “nuclear waste” has been redefined. Proponents argue that there is no such thing as waste if the spent rods can be reprocessed in order to fuel other types of plants. These efforts are particularly advanced in France, the global leader in nuclear power in 2009.

In the energy industry many observers continue to believe that nuclear power remains the best hope to power the future. The issues of safety and waste removal need to be dealt with. However, in nations with scarce supplies of energy resources, nuclear power—even with its related concerns—remains the most affordable alternative.

Oceania, Ancient

Human migrations from Southeast Asia to the South Pacific Islands of Oceania began as early as 40,000 BCE. A concentrated wave of migration about 2000 BCE produced profound environmental changes as humans introduced domesticated animals, depleted species of native fauna, and practiced agriculture resulting in deforestation and erosion. Although subsequent settlements achieved ecological balance, few who saw the region as a paradise in the 1600s realized just how fragile that balance was.

Oceania is the large region of islands and archipelagos stretching across the South Pacific Ocean. The region encompasses more than 88 million square kilometers, most of which is ocean. The total landmass in the region is 1.6 million square kilometers, made up of more than twenty-five thousand islands. Oceania is divided into three general areas: Melanesia, which includes New Guinea, the Solomon Islands, New Caledonia, Fiji, and other islands making up a belt roughly to the northeast of Australia; Micronesia, a collection of archipelagos including the Marshall Islands, the Palau Islands, Guam, and other smaller atolls (coral islands consisting of a reef surrounding a lagoon) lying to the east of the Philippines; and Polynesia, the scattered island groups including the Samoan Islands, the Cook Islands, and others lying in a large triangle running from New Zealand to Hawaii to Easter Island.

Although the history of human migration across ancient Oceania is still debated, most archeological and linguistic evidence suggests that humans colonized the region in a succession of waves emanating from Southeast Asia and moving eastward. The

earliest known human settlements in New Guinea date from around 40,000 to 35,000 BCE, approximately the same time that humans first arrived in Australia, whereas parts of the Solomon Islands lying closest to New Guinea appear to have been colonized around 26,000 BCE. By 7000 to 5000 BCE much of western Melanesia was occupied by hunter-gatherer groups, although several sites in New Guinea show evidence of early patterns of crop cultivation, including irrigation systems for growing taro (a plant grown for its edible rootstock). But the rest of Oceania remained uninhabited.

Between 2000 and 1000 BCE another wave of migration spread across Melanesia from Southeast Asia, giving rise both to new language forms and new patterns of human settlement that had a significantly greater environmental impact than the first hunter-gatherers who occupied the region. The Lapita culture, named for the distinctive pottery found at archeological sites in New Caledonia, was marked by larger settlements practicing a combination of marine and shell fishing along with an agricultural complex based on cultivation of yam, taro, and banana crops and the domestication of pigs, dogs, and chickens.

Rapid Colonization

The most important innovation of the Lapita culture, however, was advanced maritime technologies that enabled the rapid colonization of eastern Melanesia and from there, for the first time, migration northward into Micronesia and eastward into Polynesia. Larger outrigger canoes of 15 to 20 meters, coupled with improved sail technologies and refined navigation techniques, permitted colonists to cross the large

Ornamental wood carvings used on canoes, left, from New Zealand, and top and bottom right, from New Guinea. From *The Grammar of Ornament* by Owen Jones. London: Bernard Quaritch, 1910. New York Public Library.

expanses of ocean, bringing with them the crops and animals needed to establish settlements. The first known settlements in Fiji, on the eastern edge of Melanesia, date from 1500 BCE, and by 1000 BCE voyagers had crossed the several hundred kilometers of open ocean separating Fiji from the Samoan and Tonga Islands in western Polynesia. At around the same time colonists pushed northward into Micronesia, settling the Caroline and Marshall islands. Over the next fifteen hundred years the rest of Polynesia became inhabited, with humans arriving last in Hawaii around 650 CE and in New Zealand between 1000 and 1200 CE. But internal settlement and migration continued after this period, the most notable being contacts between Polynesians and South America, which resulted in the introduction of sweet potatoes as a basic crop throughout eastern Polynesia.

The establishment of human settlements on the previously isolated islands of Oceania produced profound environmental changes. None of the islands had any mammal species, with the exception of bats, before humans introduced domesticated animals. The arrival of humans was marked by sharp depletions in the numbers of native fauna through overhunting and

competition from domesticated animals, resulting in the extinction of many species. Likewise, the pioneering agriculture practiced by the colonists included extensive use of slash-and-burn techniques, which resulted in significant amounts of deforestation and corresponding erosion problems on many islands. This was especially true in parts of eastern and southern Polynesia, where a cooler and drier climate proved ill suited to the types of tropical agriculture that the arriving colonists attempted to introduce. In some extreme cases, such as Easter Island and on some of the Marquesas islands in eastern Polynesia, the arrival of humans appears to have precipitated an environmental crisis resulting in a large-scale collapse of the ecosystem and a sharp population decline or abandonment of the settlement within a century or two after colonization. Also, a continuing pressure on natural resources was one of the major forces driving the rapid migration across Oceania as colonists sought to find new islands to exploit.

Sustenance Systems

By 1500, on the eve of European arrival in the region, most of the human settlements in Oceania had developed more or less stable sustenance systems that varied according to their local climate and ecological conditions. Fishing was the most important element, and the inhabitants of Oceania practiced a wide variety of techniques, including the use of elaborate nets and traps as well as lures and harpoons. The major agricultural staples were coconuts, breadfruit, yams, and taro roots, with domesticated pigs, dogs, and chickens providing additional protein. Although many islanders continued to practice swidden (slash-and-burn) agriculture in which fields were cleared, burned, used for two to three years, and then allowed to lie fallow for up to two decades, some Oceania societies developed more extensive farming systems using terraced plots and elaborate irrigation systems. Also, the island inhabitants developed complex social structures designed to keep the population from rising beyond what could be sustained by local environmental limits.

For the European voyagers, who began visiting the South Pacific in larger numbers between 1600 and 1800, many of the Oceania islands assumed mythical status as tropical paradises. From a European perspective the relatively benign climate and apparent richness of natural resources disguised the fact that most Oceania societies rested on a fragile ecological balance that seldom lasted long after the initial contact with outsiders.

Oceans and Seas

Oceans and seas comprise 98 percent of the biosphere and cover about 70 percent of the Earth's surface. Water is circulated between the oceans and seas, the atmosphere, and the land by evaporation and precipitation, thus transporting chemicals and heat, determining the Earth's climate, and fertilizing and eroding the land. Humans depend on ocean resources, harvesting marine life, for instance, and drilling the ocean beds for oil.

The oceans of the Earth consist of four confluent (flowing together) bodies of saltwater that are contained in enormous basins on the Earth's surface. Seas are lesser bodies of saltwater. Oceans and seas cover 361 million square kilometers (70.8 percent of the Earth's surface) and 98 percent of the volume of the biosphere (the part of the world in which life can exist). Saltwater comprises about 97.2 percent of the water on the planet, the remainder being freshwater. By evaporation and precipitation water is circulated between the oceans and seas, the atmosphere, and the land. The hydrological cycle (the sequence of conditions through which water passes from vapor in the atmosphere through precipitation upon land or water surfaces and ultimately back into the atmosphere as a result of evaporation and transpiration) transports and stores chemicals and heat, determines the Earth's climate, and fertilizes and erodes the land. The average salinity of the oceans and seas is 3.5 percent, deviations being determined by evaporation and inflow of freshwater. Ocean surface temperatures around the equator may be 30°C or more, decreasing toward the poles, where seawater freezes at -2°C. Below-surface

temperature is fairly constant, decreasing to around 0°C in the deep ocean.

The largest ocean is the Pacific, which has a surface area of 166 million square kilometers, almost the size of the three other oceans together: the Atlantic (84 million square kilometers), the Indian (73 million square kilometers), and the Arctic (12 million square kilometers). The Antarctic, or Southern, Ocean is sometimes counted as the fifth ocean, consisting of the waters of the southern parts of the Pacific, Indian, and Atlantic. Sections of the oceans may be described as enclosed and marginal seas. Enclosed seas—such as the Mediterranean Sea, Hudson Bay, the White Sea, the Baltic, the Red Sea, and the Mexican Gulf—cut into continental landmasses. Marginal seas—such as the Caribbean and Bering Seas, the Sea of Okhotsk, the East China Sea, the Sea of Japan, and the North Sea—are separated from the oceans by archipelagos.

The depth of the oceans increases to about 200 meters on the continental shelves, increasing further to 3,000–4,000 meters on the ocean basin floor and to 6,000–11,000 meters in the deepest areas. The ocean bed is covered by sediments of dead marine organisms, eroded soil from the continents, and red clay.

The waters of the oceans are circulated by changing winds, air pressures, and tides. The gulf current brings warm water to the North Atlantic and thus makes it possible to sustain human life at more northerly degrees in Europe than anywhere else on the globe. The upwelling areas on the margins of the Pacific and Atlantic oceans off the coasts of Chile and Peru, California, and Namibia in Africa bring cold, nutrient-rich waters to the surface of the sea,

and the combination of sunlight and nutrient richness makes the relatively narrow continental shelves rich in marine life. But El Niño (an irregularly occurring flow of unusually warm surface water along the western coast of South America) may reverse ocean currents in the Pacific and cause abnormal climate effects both on land and sea.

Life began in the oceans, but science has incomplete knowledge of marine life-forms. About fifteen thousand species of marine fish are known, but it is estimated that five thousand species remain to be identified. The estimate of 200,000 ocean floor species of the North Atlantic alone may be low by a factor of three or four. Whereas the open oceans are blue deserts due to the lack of nutrients, the continental shelves are home to abundant marine life, and tropical coral reefs are habitats of large biodiversity (biological diversity as indicated by numbers of species of animals and plants).

Marine Resources

Humans utilize the oceans for transportation and trade, benefit from harvesting marine life, and drill the ocean bottoms for oil, thus creating the potential for exploitation and pollution.

Oceanic transportation is the cheapest and most important way to move goods between the continents, but it imposes severe environmental stress on marine habitats and biodiversity. Prior to the fifteenth century the oceans presented a formidable obstacle to contact between continents. Foraging (Paleolithic) era (2 million–10,000 BCE) migrants did spread from Africa and Eurasia to Australia and the Americas by crossing the straits of Torres and Bering; the Polynesian migrations into the Pacific islands around 2000 BCE and the Viking migration across the North Atlantic also testify to early maritime skills. However, the first contact between a major civilization and another continent was aborted in 1435 when the Chinese emperor decided to discontinue the explorations of the Chinese fleet to Africa across the Indian Ocean. The subsequent voyages of Columbus across the Atlantic from Spain to the Caribbean Sea, however, opened the way

for a sustained exchange—causing great environmental impact—with the New World. With the development of the three-masted sailing vessel and nautical instruments, global seafaring allowed an exchange of terrestrial plants and animals that had substantial consequences for the recipient countries. Marine habitat changes followed as ports and bunker areas for loading coal were extended along shorelines and estuaries and as mud-dredgers changed tidal currents and coastal erosion. In the twentieth century tanker ships impacted marine ecosystems substantially when they discharged ballast water transported over thousands of kilometers. Ballast water is one of the most serious threats to marine biodiversity and has caused irreparable changes to ecosystems. Introduced species, which have no natural enemies in new environments, can multiply and eradicate original life-forms.

Humans have harvested inshore marine environments since earliest historical times. Whales, seals, fish, crustaceans, and algae have been fished for human consumption, and seaweeds, salt, sponges, corals, and pearls have been brought to consumers for diverse uses. Today important medicines, from anticoagulants to muscle relaxants, are derived from marine snails.

Beginning in the sixteenth century, thanks to the shipping revolution, whaling and fishing operations were taken to distant islands and continents. As marine life in these distant waters was depleted, the operations became oceanic, first in the Northern Hemisphere and later in the Southern Hemisphere. These operations extinguished some life-forms, such as the Stellar's sea cow in the Bering Sea, the gray whale in the European and later the American Atlantic, and the Caribbean monk seal. The early human impacts on pristine ecosystems are believed to have been important not only to a few signal species but also to the whole ecosystem, which may have experienced regime shifts when top predators that controlled ecosystem dynamics were fished out. Today most of the commercially important fish species are exploited to the full or beyond sustainable levels. Because of such heavy fishing pressure, many of the most valuable fish stocks of the world are in decline,

A biologist from the Florida Keys National Marine Sanctuary photographs the damage done to a coral reef from a boat grounded on the reef. National Oceanic and Atmospheric Administration.

and some have become locally extinct. The most dramatic case is the Newfoundland cod fishery, which collapsed in 1991, causing not only enormous and possibly irreparable harm to the ecosystem but also the disappearance of the very means of existence for many people in Atlantic Canada.

Commercial exploitation of minerals in the ocean bed is only beginning and is expected to increase dramatically in the twenty-first century. The ocean bed contains energy in the form of oil and natural gas, and minerals such as sodium chloride (salt), manganese, titanium, phosphate, and gold are found in the oceans. People also have begun to utilize tidal power from the oceans. The development of industrialized societies has increased the discharge of sewage and other waste into the oceans and also has created the phenomenon of oil spills.

About two-thirds of the world's population live within 60 kilometers of a coast, and almost one-half of the world's cities with more than 1 million people are located near estuaries. This settlement pattern is a result of people choosing the oceans instead of agriculture as a source of food and employment; the oceans also have provided access to communication, transportation, and trade. However, people have had a prejudice against coastal settlement in some historical periods. The most marked instance of this prejudice occurred in many Neolithic (8000–5500 BCE) cultures with the introduction of agriculture, which increased the incentive to settle virgin inland territories. The nineteenth-century frontier movement of North America was also decidedly terrestrial, although migrants had to cross the Atlantic to pursue opportunities. In contrast, other colonizing experiences, such as the ancient Phoenician and Greek city-states, were decidedly maritime.

The French historian Fernand Braudel (1949) was the first to attempt a history of an enclosed sea—in this case, the Mediterranean—as a natural environment and a highroad for communication and cultural exchange. He argued that the common environmental conditions prevailing on the coasts of the Mediterranean provided the basis for a common culture. He showed how life in the mountains, plains, and coastal lowlands related with the sea across European and Arabic civilizations, and he stressed that the seaways were a key to the growth of the European economy. Braudel perceived of Europe as three regions: the Mediterranean, the Continent, and the Second Mediterranean of Europe; that is, the North Sea and the Baltic, or collectively the Northern Seas. Many other historians have since recognized that if the Mediterranean shores had a common culture, the same would hold true for other seas, with differences due to natural circumstances (such as enclosed or marginal character of the sea and accessibility of its shores) and historical experiences. The problem with the arguments of such historians is that they tend to list those aspects that the shores of a sea have in common but do not compare contacts inside and outside of the regional system.

It isn't the oceans which cut us off from the world—it's the American way of looking at things. • **Henry Miller (1891–1980)**

Other approaches to the question of the role of oceans in human history have stressed the problems of overcoming distance. This is the dominant theme, of course, in the study of the Age of Exploration (c. 1491–1750), but it also resonates in the study of the more recent history of U.S. and European relations and most forcefully in the study of the history of Australia, which until the age of global airlines lived under the “tyranny of distance”—the fact that any visit abroad required weeks if not months of sea travel.

In the age before modern transport systems, sea transport was generally cheaper than land transport but not faster. Ship movements had many natural and unpredictable constraints. Delays of weeks occurred frequently because of unfavorable winds, and although some skippers would travel day and night because of a good knowledge of local waters, most dared sail only in daytime. Calculations of actual distances traveled by ships indicate that in spite of good winds sometimes bringing a ship's speed to 10 knots per hour (18 kilometers per hour), the distance covered during full trips, including the time spent waiting at anchor, seldom averaged more than 1 or 2 nautical miles (1.85–3.7 kilometers) per hour spent at sea. The distance covered per day thus works out to 45–90 kilometers. This calculation corresponds with actual travel distances on land. Whereas one cartload normally contained only twelve to eighteen barrels of grain or fish, even a small shipload might contain many times more. A typical ship of two hundred tonnes required a maximum crew of only ten men. The person-to-ton ratio would thus be 1:10 for the ship as against 1:1 for the cart, whereas distance traveled per day would be the same. Thus coastal urban markets received supplies by sea at a rate competitive with supplies from inland. A recent study of medieval England showed a ratio 1:4:8 for transport costs by sea, river, and road. Because the efficiency of land transport did not develop to the same pace as productivity increased in other trades such as agriculture, land transport costs grew relative to other costs until the eighteenth century.

The sea did not necessarily facilitate cultural impulses, such as aesthetic, dietary, or religious preferences, in the same way. The transportation of information and cultural impulses was not related to bulk freight rates but rather relied as much on individual travel patterns, most often by foot or horseback. Although enclosed and marginal seas may often have contained a well-developed trade and transport infrastructure, cultural relations do not necessarily mirror this and indeed may show quite different patterns of communication. Nevertheless, during the age of sail, roughly from 1500 to 1850, maritime regions played a decisive role in many parts of the world. Coastal stretches of enclosed or marginal seas had an unusual concentration of maritime capital and labor that made possible the development of a distinctively maritime culture. This concentration was often based on the availability of timber for shipbuilding, although lack of forests did not preclude some regions rising to maritime preeminence.

The industrial transport revolution of the nineteenth century greatly enhanced long-distance and even global travel, but it lessened the importance of regional transport economics. Improved roads, railways, and steam shipping created a world market for many more goods than before, and regional markets gave way to the global market. Most small maritime communities were not able to raise the capital needed to participate in the global transport market, and as a result the coastal landscape changed from a string of human settlements to a few port towns with a concentration of maritime capital. In the industrial age, therefore, the age of regional seascapes came to an end.

Port towns are the nodes of the maritime transport system. The first port towns were well developed in the Mediterranean three thousand years ago. A port town may have its own home fleet, the crucial characteristic being that the town is a hub of inland and seaborne trade. Port towns tend therefore to utilize natural assets such as ease of multimodal transportation (land, river, and sea transport), access to a productive hinterland and a market, and strategic advantages such as control of waterways. Port towns provide access to the economic arteries of a country

Sea levels have been rising since 1900 with the rate of change accelerating in the last half century. Researchers from NOAA's National Geodetic Survey conduct a shoreline survey. National Oceanic and Atmospheric Administration.

and therefore have historically been keenly regulated both for fiscal and military purposes. Occasionally they have gained full or partial sovereignty, as did the Italian city-states and the towns of the Hanseatic League, or have dominated a territorial state, such as the Netherlands in the sixteenth to eighteenth centuries, but most often they have been controlled by larger territorial powers. With the increased demands of shipping in the nineteenth century came the need for a larger workforce, and port towns became densely populated with laborers. The towns themselves sprawled along wharves and quays to become unwieldy entities, congested and heavily polluted. As a result of the spread of coal-fired steamer traffic in the second half of the nineteenth century, however, adhering to strict time schedules became possible and of utmost importance. Thus new infrastructures of bunker ports and dedicated quays sprang up along the coasts to facilitate the steamers. Wind-powered ships continued to defeat the steam ships as long as a line of bunker ports did not

dot the margins of the seas, but eventually the steam ships took possession of more and more sea routes so that by the early twentieth century the slow windjammers to Australia were the last to give in.

By that time diesel engines were being introduced, and by the 1950s coal was all but given up. At that point, passenger ships lost their edge in the oceanic transportation of people to the airlines, but a new era for the shipping of goods more than compensated for the loss to ship owners. In the first half of the twentieth century ships were designed to provide optimum cargo facilities and quicker turn-around times in ports. The Argentine meat industry and the Canary Island banana trade demanded refrigerated ships, and the oil industry gave rise to tanker ships. By the 1960s a design revolution took place, introducing the all-purpose shipping container, a metal box that could be refrigerated or otherwise modified and that conformed to standard measures and therefore allowed for convenient storage on board. The container ship became the vehicle for the globalization of trade, which severed the links between origin of resource, modification and packaging, and consumption.

To achieve optimum handling the once-prolific system of ocean ports has been minimized to a system of a few world ports that are the nodes of a few big container lines. Servicing the system are a number of feeder lines from lesser ports and a prolific number of trucking services that ensure that the individual container is brought to its final destination.

The environmental impact of the globalized container system is enormous. Although the system undoubtedly brings rationalization of the economic system, it is dependent on the availability of abundant and cheap energy, which will marginalize, for example, the costs of moving east Asian tiger prawns to Morocco to be peeled by cheap labor before they are moved to Germany to be packaged before they are eventually consumed in, for example, a restaurant in Paris.

Sea Law and Sea Powers

The oceans and seas have long been governed by law. Hugo Grotius, a Dutch lawyer, historian, and

theologian laid down the first principles for an international law of the seas his 1609 treatise *Mare Liberum* (The Free Sea). He observed that the sea is an inexhaustible, common property and that all should have open access to it. These principles were adhered to in theory by all major European naval states and eventually were introduced as the guiding principles for access to all oceans and seas. Most states claimed dominion over territorial or coastal waters, but commercial ships were allowed free passage. The most important exception to this principle was the Danish Sound, providing access between the North Sea and the Baltic. The Danish government in 1857 lifted its toll on the sound and the right of inspection only after international treaty and compensation. The shooting range of a cannon originally defined the width of territorial waters, but during the nineteenth century a 3-nautical-mile (5.5 kilometers) limit was increasingly accepted and laid down in international treaties. After World War II, U.S. President Harry Truman claimed wider rights to economic interests on the North American continental shelf against Japan, and Chile and Peru claimed a 200-nautical-mile (370 kilometers) exclusive fishing zone off the coasts against U.S. tuna fishers. Iceland followed soon after with claims to exclude British fishers from Icelandic waters. Oil and fisheries were the main economic motives for these claims. In 1958 the United Nations called the first International Conference on the Law of the Sea to establish a new consensus on sea law. The conference extended territorial limits to 12 nautical miles (22 kilometers) but failed to settle the issue. A second conference in 1960 made little progress. During the 1960s and 1970s positions changed dramatically. It became much more evident that the supplies of fish stocks were limited and that depletion was becoming more prevalent. Attempts to manage resources through international bodies were proving to be largely ineffective. Many coastal states, both developed and developing, felt increasingly threatened by the large fleets of distant-water states off their coasts. Simultaneously, the issue of control over the mineral resources in the deep ocean beds raised the demands of developing states for a more equitable distribution

of ocean wealth. The third international conference, which lasted from 1974 to 1982, resulted in a convention that is internationally recognized. The main innovation was the declaration of the right of coastal states to a 200-nautical mile “extended economic zone” (EEZ), which may be claimed by a coastal state for all mineral and living resources. The convention was signed by 157 states, while the United States, United Kingdom, and Germany took exception to the stipulations on seabed mineral resources. The EEZs represent the largest redistribution of territorial jurisdiction since nineteenth century colonialism.

The choice of 200 nautical miles as a limit for jurisdiction has no relevance to ecosystems or indeed to the distribution of mineral wealth but is simply a result of international negotiations. Whatever the imperfections of the convention, it has, however, provided coastal states with the authority to manage the resources within their zone. The short history of EEZs shows that they may be implemented to promote conservation interests in addition to the national economic interests for which they were designed.

Management and Protection

Whereas the law of the sea provides only a broad framework for international regulation of matters relating to oceans and seas, nation-states have developed intricate policies and institutions that impact the oceans. Two policies for the marine environment have been developed in recent years: integrated coastal zone management (ICZM) and marine protected areas (MPA). The specific policies that deal with issues such as watersheds and coastal development to seabed utilization by their very nature fail to take issue with the complete set of challenges that confronts people when they seek to manage, preserve, and develop the marine environment. This is the justification for the development of integrated coastal zone management. ICZM has developed as a cross-cutting policy for coastal and inshore management concerns since the 1980s, but it is implemented only to a limited degree in most countries. Marine protected areas have been designated throughout the world as areas where

human access is restricted in order to conserve marine habitats. Coral reefs, fragile spawning areas, and hot spots of marine biodiversity have often been selected, but by 2000 only about 1 percent of the oceans were protected even by limited restrictions. The oceans and seas are still subject to open access and unrestricted human practices in most regions of the world, and the underwater world remains the last frontier, still to a large degree unexplored by humans.

Oil

Oil, or black gold, is one of the most contentious commodities in recent history. As the most important source of energy in the twentieth century, oil has been a key ingredient in transforming agriculture and transport, and with them, social and economic life. But oil has also been a source of domestic and international conflict, and is closely implicated in environmental degradation.

No commodity or industry had a greater impact on world history in the twentieth century than petroleum, or oil, a complex mixture of hydrocarbons that had their ultimate origin in plants and animals that lived and died hundreds of millions of years ago. Oil production and use has transformed social and economic life and has had a deep and lasting impact on the environment. Control of oil has helped determine the outcome of major wars and has been a central element in U.S. global power.

History of Oil Use

Oil from natural seepages was used as early as 3000 BCE in Mesopotamia and China for heating, lighting, medicine, ship caulking, and road building. Later, oil was a key ingredient in Greek fire, a flammable mixture of petroleum and lime used in warfare. Widespread oil use did not occur until the mid-nineteenth century, however, when the development of techniques for refining crude petroleum created new uses for oil. The development of hard-rock drilling for oil also greatly expanded oil production. Kerosene refined from crude petroleum quickly became a major source of illumination, and

petroleum-based lubricants replaced vegetable oils, whale oil, and animal tallow.

Used mainly for illumination in the nineteenth century, oil became an integral part of modern life in the twentieth century. Just as electricity began to overtake kerosene as the main source of illumination, at least in urban areas, the development of the oil-powered internal combustion engine in the late nineteenth century and its almost universal adoption in the transportation sector over the course of the twentieth century created vast new markets for oil. Aided by improvements in refining techniques, oil became the fuel of choice for the automobiles, trucks, ships, and airplanes that revolutionized transportation and transformed the physical, economic, and social landscapes of societies all over the world. Oil-powered machinery and petrochemical-based pesticides, herbicides, and fertilizers also sparked unprecedented increases in agricultural production. In particular, the development in 1909 of a method to synthesize ammonia, first from coal and later from natural gas, allowed massive expansion in the use of inorganic fertilizers resulting in dramatic increases in food production, and with it, water pollution. By the end of the twentieth century, oil accounted for around forty percent of global energy consumption (including over ninety percent of transportation energy use) and was the most important commodity in international trade both in terms of mass and value.

Environmental Impact of Oil Use

Drilling for oil, transporting and refining oil, and burning oil has had a significant impact on the environment. Fossil fuel combustion, of which oil is a

The use of solar energy has not been opened up because the oil industry does not own the sun. • **Ralph Nader (b. 1934)**

major component, puts far more carbon dioxide into the atmosphere than the world's oceans, soils, and biomass can absorb, and probably has affected the Earth's climate. In December 1997, the developed countries agreed, in the Kyoto Accords on Climate Control, to reduce their emissions of global warming gases. (Despite the aims of the Kyoto Protocol, which expires in 2012, global emissions of greenhouse gases have continued to increase. In December 2009, participants at the United Nations Climate Change Conference in Copenhagen, Denmark, failed to reach a binding agreement about replacing the Kyoto Protocol, but as of April negotiators were seeking to extend and complement the existing treaty at the 2010 conference in Cancun.) Oil production and oil-derived products (including products of the petrochemical industry) have also contributed significantly to air, water, and soil pollution, both directly and indirectly. Oil-powered technologies have allowed vast increases in mining and logging activities, for example, with major environmental consequences.

Oil and Military Power

Oil became essential to military power in the early twentieth century, when the navies of the great powers, led by Great Britain and the United States, began to switch from coal to oil as fuel. Although the navies of the great powers played a relatively minor role in World War I, oil and the internal combustion engine heralded a revolution in mobility on the land, the sea, and in the air.

Oil was crucial to the origins and outcome of World War II. Hitler's desire to gain control of oil for his heavily mechanized war machine was an important factor behind his decision to invade the Soviet Union. Japan was dependent on the United States for around 80 percent of its oil needs, and the U.S. decision in the summer of 1941 to cut off oil exports to Japan presented Japanese leaders with the option of going to war to seize oil supplies in the Netherlands East Indies or bowing to U.S. pressure. All the main weapons systems of World War II were oil-powered—surface warships (including aircraft

carriers), submarines, airplanes (including long-range bombers), tanks, and a large portion of sea and land transport. Oil was also used in the manufacture of munitions and synthetic rubber. Access to ample supplies of oil was a significant source of allied strength, while German and Japanese failure to gain access to oil was an important factor in their defeat.

Although the development of nuclear weapons and later ballistic missiles fundamentally altered the nature of warfare, oil-powered forces, and hence oil, remained central to military power. Despite the development of nuclear-powered warships (mainly aircraft carriers and submarines), most of the world's warships still rely on oil, as do aircraft, armor, and transport. In addition, each new generation of weapons has required more oil than its predecessors.

Oil and World Power

While the demand for oil has been worldwide, the greatest sources of supply have been few and far between, and often in developing or underdeveloped countries. Disputes over ownership, access, and price have made oil a source of international conflict, particularly in the Middle East, which contains around two-thirds of known world oil reserves. Created in 1960, the Organization of the Petroleum Exporting Countries (OPEC) is a cartel of oil producing nations that has considerable influence in determining the rate of oil production and with it the price of oil. OPEC countries account for around two-thirds of the world's known oil reserves and around one-third of world oil production.

In the first half of the twentieth century, the United States, blessed with a thriving domestic oil industry and firmly entrenched in the oil-rich region of the Gulf of Mexico and the Caribbean, controlled more than enough oil to meet its own needs and to fuel the allied war effort in both world wars. Following World War II, the United States made maintaining Western access to the oil riches of the Middle East a key element in its foreign policy. Control of oil, in turn, helped the United States fuel economic recovery

in Western Europe and Japan and sustain the cohesion of the Western alliance.

The Soviet Union, in contrast, was unable to convert its control of extensive domestic oil supplies into political influence outside of Eastern Europe. In addition, despite geographical proximity, extensive efforts, and widespread anti-Western sentiment in Iran and the Arab world, the Soviets were unable to dislodge the United States from the Middle East. The Soviets benefited briefly from higher oil prices in the 1970s, but the collapse of world oil prices in the mid-1980s undermined efforts by Soviet reformers to use the earnings from oil exports to ease the transition from a command economy to a market economy while maintaining social welfare programs. In the post-Cold War twenty-first century, oil has allowed Russia to finance military modernization programs and reclaim some of its lost prestige as a world power. Similarly, oil reserves partially explain Venezuela's sometimes bold stance in trans-American political affairs.

Peak Oil

Peak oil refers to the point in time when we reach the maximum rate of world oil extraction. Following the plateau, the rate of oil production begins to tail off into terminal decline. Optimistic forecasts predict that oil will peak in production sometime around 2020. Pessimists claim that peak oil occurred sometime in the first decade of the twenty-first century. In all likelihood we will only become aware of the timing of peak oil after the fact. Precisely what effect peak oil will have on prices, consumption, and world affairs more generally is difficult to determine. It depends in part on the viability of alternative energies.

The central role of oil in transportation and agriculture, and the absence of alternative energy sources that possess oil's versatility, high energy density, and easy transportability, mean that oil prices and competition for access to oil will continue to be important

issues in world affairs. Whether or not social, economic, and political patterns based on high levels of oil use are sustainable on the basis of world oil reserves, environmental scientists warn that they are not sustainable ecologically—that continuation of high levels of oil consumption will have severe and possibly irreversible impacts on the earth's environment.

Oil Spills

Oil in myriad forms has been used for hundreds of purposes for at least six thousand years. Oil spills occur naturally and as a result of oil exploration, transportation, and processing. Several disasters have led to more stringent environmental standards, such as double-hulled ships. The drilling-platform explosion and subsequent oil leak in the Gulf of Mexico in April 2010 has brought renewed global attention to the dangers of oil spills.

Oil is a main source of energy. Because it is unevenly distributed in the world, it must be transported on the seas and in pipelines to distant lands. Although the major oil transport and transfer activities occur on the seas, ports, and rivers, they are not limited to these areas. Accidental spills can occur wherever oil is drilled, stored, handled, refined, transported, and transferred. These spills can be either massive and catastrophic or chronic. Few other environmental problems are as common or ubiquitous or have the potential for immediate environmental damage and long-range effects. Recent or dramatic oil spills include those involving the ships *Amoco Cadiz*, *Exxon Valdez*, and *Sea Empress*, and the massive intentional oil spills during the Gulf War. As this encyclopedia goes to press, an oil spill resulting from the explosion of the British Petroleum drilling platform *Deepwater Horizon* is still flowing into the Gulf of Mexico from 64 kilometers (40 miles) off the coast of Louisiana; it is considered to be the worst environmental disaster in U.S. history.

Crude petroleum or oil is a liquid or semiliquid mixture of hydrocarbon compounds that contains sulfur, oxygen, nitrogen, other elements, and metals.

The hydrocarbons are the decayed remains of small marine animals and plants that flourished in the shallow inland seas that once covered large areas of the continents. Over hundreds of thousands of years, the dead remains of these tiny organisms drifted to the sea bottom. Covered by mud, this organic matter changed into the complicated hydrocarbons we call petroleum. For the past 600 million years, incompletely decayed plant and animal remains were buried under thick layers of rock, often accumulating one layer at a time. Because petroleum, natural gas, and coal formed from organisms that lived millions of years ago, they are called fossil fuels.

Since the Paleozoic era (from 570 to 245 million years ago), this organic matter has been slowly moving to more porous and permeable rocks, such as sandstone and siltstones, where it was trapped. The oil accumulates because of the presence of impermeable rock lying over these reservoirs. Some oil fields extend laterally in the rock over several kilometers and may be several hundred meters deep. Some oil enters the oceans through natural seeps, and these natural oil spills can have massive effects on the organisms living nearby.

Some of the hydrocarbon products of petroleum include dissolved natural gas, gasoline, benzene, naphtha, kerosene, diesel fuel and light heating oils, heavy heating oils, and tars of various weights. Petroleum yields these products through elaborate refining processes. They are then further refined and combined into other products such as solvents, paints, asphalt, plastics, synthetic rubber, fibers, soaps and cleansing agents, waxes and jellies, medicines, explosives, and fertilizers. Oil spills can occur during the refining process or during transport.

Sir Lawrence Alma-Tadema, *The Finding of Moses* (1904). Oil on canvas. Nile River boats were caulked with asphalt, and when the infant Moses was set adrift he was cradled in a raft of bulrushes “daubed with pitch.” Despite the fanciful depiction, Alma-Tadema’s painting was renowned for archeologically precise details.

History of Small Oil Spills

For over six thousand years people have used asphalt, pitch (bitumen), and liquid oil in numerous and ingenious ways. People living in river valleys of ancient Mesopotamia used local asphalt from hand-dug pits as building cement and caulking for boats. The legend of the flood described in the Book of Genesis records that the ark was well caulked. Nile River boats were caulked with asphalt, and the infant Moses was cradled in a raft of bulrushes “daubed with pitch” when he was set adrift. The Elamites, Chaldeans, Akkadians, and Sumerians mined shallow deposits of oil-derived pitch or asphalt to export to Egypt to preserve the mummies of great kings and queens and to make mosaics to adorn their coffins. (Ancient Egyptians used liquid oil as a purgative and wound dressing, since it aided the healing process and kept wounds clean.) Archeological remains in Khuzestan, Iran, show that asphalt was commonly used for

bonding and jewel setting during the Sumerian epoch (4000 BCE). Asphalt served as cement in the Tower of Babel and in the walls and columns of early Babylonian temples. As early as 600 BCE the Babylonians set clay cones and tiny semiprecious stones in bitumen to form elaborate mosaics.

Soon fossil fuels were recognized for their light-giving properties: according to the Greek biographer Plutarch, in about 331 BCE Alexander the Great was impressed by the sight of a continuous flame issuing from the Earth in Kirkuk, Iraq, probably a natural gas seep set ablaze. The Romans used oil lamps in the first century BCE. The Chinese first used oil as a fuel around 200 CE, employing pulleys and hand labor to suction the oil from the ground through pipes. Oil spills resulting from these uses were small and limited in scope.

Oil was quickly adopted for military purposes, especially naval skirmishes, which resulted in larger spills. Oil-filled trenches were set aflame to defend cities in ancient times. The Persians developed the

first distilling processes to obtain flammable products for use in battle, catapulting arrows wrapped in oil-soaked cloths toward their Greek enemies during the siege of Athens in 480 BCE. At close range, what eventually became known as Greek fire was propelled through tubes onto Persian ships attacking Constantinople in 673 CE, resulting in the Greek's near destruction of the fleet. The Byzantines used liquid fire against the Muslims in the seventh and eighth centuries; thrown onto enemy ships from pots or tubes, liquid fire (probably some combination of oil, naphtha, and chemical substances such as sulfur and quicklime), caused extensive damage and terror. (The exact "recipe" remains unknown, but historians believe it was passed down from emperor to emperor.) The Saracens used Greek fire against St. Louis at the crusades, and the Knights of St. John used it against the invading Turks at Malta. The Mongols also burned petroleum products in their siege of Central Asia. Bukhara in western Asia fell in 1220 because Chinggis (Genghis) Khan threw pots full of naphtha and fire at the gates of the castle, and it burst into flame. People were forced to flee the city or else die.

During the Renaissance, the transport of oil developed, leading to more significant oil spills in the wake of trade. In 1726 Peter the Great of Russia issued ordinances regulating the transport of

oil from Baku on the Caspian Sea, by boat, up the Volga River. Oil became a valued commodity to barter, trade, or steal. In the New World, the natives of Venezuela caulked boats and hand-woven baskets with asphalt, and liquid oil was used for medicine and lighting. Native North Americans used oil in magic, medicines, and paints. The first barrel of Venezuelan oil was exported to Spain in 1539 to alleviate the gout of Emperor Charles V.

The modern era of oil transportation began in 1820 when a small-bore lead pipe was used to transport natural gas from a seep near Fredonia, New York, to nearby consumers, including the local hotel. From this time on, the possibility of oil spills due directly to transport and transfer increased with the decades.

The Modern Oil Spill Era

The majority of known oil reserves are in the Middle East, followed by North America. The Organization of Petroleum Exporting Countries (OPEC) has the greatest reserves, with Saudi Arabia leading the member nations.

The global distribution of oil deposits influences production and transport patterns and thereby determines the potential distribution of oil spills. World oil production rose from 450 million metric tons in 1950 to 2.7 billion metric tons by 1996 and continues to rise slowly. Oil spills rise along with production.

The primary method of transportation of oil is by oil tanker, and traditional shipping lanes have developed between the oil-producing countries and the oil-importing countries. At present, major oil routes go from the Middle East to Japan, Europe, and the United

This sculpted goat, excavated from the royal cemetery in the Sumerian city of Ur, is made from gold, silver, lapis lazuli, copper, shell, red limestone, and bitumen (pitch). Ancient civilizations also used pitch and asphalt as mosaic "cement." The University Museum, Philadelphia, Pennsylvania.

Scientists measure a dead Kemp's ridley sea turtle on the Gulf Coast of Mississippi. This endangered species is especially at risk in an oil spill because it feeds indiscriminately and has no behavioral mechanism for avoiding oiled waters. National Oceanic and Atmospheric Administration.

States. Oil is also transported through pipes over vast distances to refineries. Oil spills occur mainly along these oceanic and land routes and along the shores where oil transfers take place. Small spills occur during the transfer of oil from tanker to tanker, from tanker to refinery, from damaged, underground pipes, and around oil refineries and storage facilities. About 7.56 billion liters of oil enter the oceans from spills and other accidents each year.

Large spills usually occur during tanker accidents. With the increase in the size of oil tankers, the potential for accidents has increased. The tankers of the 1880s had a capacity of 3,000 metric tons, compared to 16,500 in 1945, 115,000 in 1962, and 517,000 in 1977. In the modern era of tankers, considered to be post-1989 and the *Exxon Valdez* disaster, tankers are commonly classified by size and the sea lanes they travel: Panamax and Suezmax tankers, for instance, are the largest crude carriers that will “fit” through the Panama and Suez canals, respectively. Recent requirements and conventions, such as the International Maritime Organization’s International Convention for the Prevention of Pollution from Ships, dictate that only double-hulled ships can ply international waters; this should decrease the number of tanker spills in the future, although not all regulations and conventions are legally binding. Oil spill-susceptible single-hulled

ships are due to be taken out of service worldwide by 2010, although it remains to be seen whether this will happen or not.

Although the large oil spills receive media attention, only about 4 percent of oil entering the oceans comes from tanker accidents. Another 25 percent enters from tanker operations, 14 percent from other transport accidents, and 34 percent from rivers and estuaries. About 11 percent of the oil entering the oceans comes from natural seeps.

Major Spills

Since 1978 there has been a steady increase in the number of small spills, whereas the number of large spills has remained relatively constant. One to three spills of over 38 million liters happen each year. One or two catastrophic accidents in any given year can substantially increase the amount of oil spilled onto the land and into the oceans. The small spills of less than 378,000 liters apiece add up to about 38 million liters a year worldwide. Even without major disasters, large quantities of oil spill into marine and inland habitats.

The largest spill on record dumped 907 million liters into the Persian Gulf in 1991 as Iraqi forces sabotaged hundreds of wells, oil terminals, and tankers when they withdrew from their position in Kuwait during the Gulf War, but most spills are

After the *Exxon Valdez* spill in Prince William Sound, workers attempted to clean the shoreline using high-pressure, hot-water washes in which oil is hosed from the beaches, collected within floating boom, and then skimmed from the surface of the water. National Oceanic and Atmospheric Administration.

smaller. The 1970s were the worst decade on record in terms of both numbers of oil spills and quantities of oil spilled, according to the International Tanker Owners Pollution Federation (ITOPF). Other large spills have included the oil well Ixtoc-1 in Mexico (529 million liters, 1979), Norwruz Field in Arabia (302 million liters, 1980), Fergana Valley in Uzbekistan (302 million liters, 1992), *Castillo de Bellver* off South Africa (294 million liters, 1983), and the *Amoco Cadiz* off France (257 million liters, 1978). All other spills were less than 189 million liters each. The *Exxon Valdez* spill of 1989 in Alaska was twenty-eighth on the list, with 41 million liters, although the spill was particularly devastating because of the fragile nature of the affected sub-Arctic ecosystem. Because the 2010 Gulf of Mexico spill is not yet fully contained at this writing, nearly three months after the explosion of the *Deepwater Horizon* platform—and because the estimates of how much oil spilled per day varied so dramatically, depending on the source—determining its place in this world hierarchy is premature. According to Kayvan Farzaneh, writing in the 30 April 2010 issue of *Foreign Policy*, the Gulf spill would clearly dwarf the *Exxon Valdez* disaster, however, based on average estimates of 5,000 barrels spilled a day for 90 days, or about 75 million liters.

Effects of Oil Spills

Animals and plants and the nonliving parts of ecosystems are not equally vulnerable to oil spills. Some

plants are fragile and have narrow habitat ranges, and they grow only in isolated sites. Some animals are very specialized, living in only a few places or eating only a few kinds of foods. Such species are particularly vulnerable to even small oil spills. Plants and animals in Arctic environments are fragile because of the limited growing season, limited diversity, and slow decay of the oil itself.

Other species are generalists, with wide tolerances for different environmental conditions, broad food requirements, and large geographical distributions. Such animals and plants are very adaptable and often can recover quickly from an oil spill, although the initial death toll may be high. Still other animals, such as some birds, fish, and mammals, can move away from a spill if its spread is slow.

Factors that determine whether an oil spill has devastating effects on plants and animals include size of the spill, type of oil, time of the spill (particularly in relation to the lifecycle of the organisms), vulnerability of particular plants and animals, and the vulnerability of particular ecosystems. Location of a spill can determine effects. In spills in intertidal marshes or estuaries where there is little tidal flow, there is a reduced opportunity for the oil to be carried out to sea, where dilution can blunt the effects. Oil often concentrates at the edge of marshes where there is also a high concentration of invertebrates, young fish, and foraging birds. Many invertebrates do not have the ability to move or move only very

Oil is like a wild animal. Whoever captures it has it. • J. Paul Getty (1892–1976)

short distances, making them particularly vulnerable to oil.

The timing of a spill is critical. A spill that occurs during the migratory season of birds, fish, or mammals may result in unusually high exposure of vast numbers of animals. A spill during the spawning season of invertebrates or fish can eliminate reproduction for a season, and a spill during the migration season of marine mammals can kill or weaken a significant portion of the local populations of seals, sea lions, sea otters, whales, and other mammals. Seabirds are particularly at risk because they spend most of their time in the oceans or in estuaries, where massive oil spills usually occur. Seabirds also nest in large colonies of hundreds or thousands, where an oil spill can “oil” or kill hundreds at a time. Oiled parents bring oil back to the nests, killing eggs or young chicks. Because they are so visible, birds often serve as bio-indicators of the severity of oil spills, although only a fraction of the birds that die in oceanic or coastal oil spills are ever recovered. Spills that occur during hurricane or cyclone seasons can be particularly hard to clean up.

People can be injured or become ill during oil spills or during the cleanup and can become ill by consuming oil-tainted fish or shellfish. Oil spill accidents can result in the death of workers on the tanker, refinery, or pipeline or the people employed in cleanup. Oil spills often occur during bad weather and stormy seas, making the hazards for the tanker crew more severe.

The effect of oil spills on fishing communities can be devastating. Fishing communities are affected both in the short term and the long term. For many weeks or months the fish are tainted or contaminated, grounding the fisheries completely. The effects of oil on the fish may result in lower harvests for years after the oil has disappeared. Fishing losses were documented for at least six years after the *Exxon Valdez* spill. Fishers lost income because of the low yields and restricted fishing areas, and guides and hotels lost money because recreational fishers did not come back for many years. Fishers and guides lost their jobs and their lifestyle. Native

American communities also lost their ability to harvest traditional resources, including fish and shellfish, resulting in a permanent change in their lives. The effects cascaded because much of the local economy depended upon fishing and tourism. The effects of oil spills on aesthetics and existence values, as well as on fishing and tourism, are massive and extensive. The full effects of the ongoing British Petroleum *Deepwater Horizon* spill on the fragile ecosystems of the Gulf of Mexico cannot yet be calculated as of this writing, but the long- and short-term consequences on the wildlife and fishing and tourism industries will be catastrophic indeed. A synchronous oil spill on the other side of the planet, at Dalian, an important coastal resort city in China, made it clear that disasters resulting from the continued search for concentrated forms of ancient biological life—fossil fuels—affect ecosystems, human health, and regional economies. If there is a silver lining, it is to be hoped that the disaster will lead to more robust, legally binding international laws regarding the exploration, transportation, and processing of the world’s oil, and a renewed sense of urgency of finding alternative sources of energy.

Organization of American States (OAS)

The Organization of American States (OAS) is the world's oldest regional organization, dating to 1889–90. The stated primary concerns of the OAS are promoting democracy, defending human rights, multilateral security, and economic and social development. Today the OAS membership comprises the thirty-five independent states of the Americas; another sixty-two states have permanent observer status, as has the European Union.

The Organization of American States (OAS), headquartered in Washington, D.C., is an international organization and successor to the Pan-American Union (PAU), which was founded in 1889–1890 at the First International American Conference and originally called the Commercial Bureau of the American Republics. The conferences sought to deal with commercial and legal issues in the Americas. The OAS is organized into the Office of the Secretary General, the General Assembly, a Permanent Council, and the Inter-American Council for Integral Development. There are specialized organizations and agencies to deal with such varied issues as drug control, telecommunications, human rights, and agriculture.

In the spring of 1948 in Bogotá, Colombia, at the Ninth International American Conference, delegates representing twenty-one American countries signed the OAS Charter and the American Declaration of the Rights and Duties of Man, the first international expression of human rights principles. The OAS, which built upon the Inter-American Treaty of Reciprocal Assistance, reflected the onset of the Cold War, which remained the United States of America's

preoccupation for more than a quarter century. That is, the OAS was part of a broad U.S. effort, along with the Truman Doctrine, the Marshall Plan, and NATO, all in Europe, to organize friendly countries to work together, to better the lives of their respective peoples, and to resist the Soviet Union and international Communism. The transition from PAU to OAS went smoothly, and the PAU director general, Alberto Lleras Camargo, became the first secretary general of the OAS. The non-signers were mostly British dominions and British crown colonies in the Americas still tied to the British Commonwealth. In subsequent years, fifteen countries have joined the original twenty-one signatories, the last being Guyana in 1991.

The OAS has clear goals, including working with the United Nations to promote hemispheric peace, supporting economic development, encouraging cultural and social interactions, and protecting the sovereignty and independence of American states. Article 1 of the Charter states that aims of the Organization and its members is “to achieve an order of peace and justice, to promote their solidarity, to strengthen their collaboration, and to defend their sovereignty, their territorial integrity, and their independence.” Article 2 outlines eight essential purposes:

- a) to strengthen the peace and security of the continent;
- b) to promote and consolidate representative democracy, with due respect for the principle of nonintervention;
- c) to prevent possible causes of difficulties and to ensure the pacific settlement of disputes that may arise among the Member States;

- d) to provide for common action on the part of those States in the event of aggression;
- e) to seek the solution of political, juridical, and economic problems that may arise among them;
- f) to promote, by cooperative action, their economic, social, and cultural development;
- g) to eradicate extreme poverty, which constitutes an obstacle to the full democratic development of the peoples of the hemisphere; and
- h) to achieve an effective limitation of conventional weapons that will make it possible to devote the largest amount of resources to the economic and social development of the Member States.

There certainly have been tensions and differences in the organization and among member states, reflecting in part differences between the United States, caught up in Cold War bipolarization, and Latin American nations, who feared American power and interference. Nevertheless, the OAS has enjoyed some success in maintaining peace in the Americas. For example, it helped end border fighting between Costa Rica and Nicaragua in 1948–1949 and 1955 and resolve the 1969 “*Soccer War*” between Honduras and El Salvador.

But there have been challenges as well. In 1959, Fidel Castro led a movement that overthrew the corrupt regime of the dictator Fulgencio Batista. Three years later, after Castro announced he was a Marxist-Leninist, the United States moved to have Cuba expelled from the OAS on charges of subversion, and in 1964 the OAS imposed a trade boycott. But by the 1990s, virtually every OAS member state save for the United States had restored diplomatic relations and resumed trade with Cuba. And now in the twenty-first century even the U.S. is looking to soften its stance towards Cuba. On 3 June 2009, the OAS resolved to repeal a 1962 Resolution excluding Cuba from the workings of the Organization. More recently, on 5 July 2009, the Organization unanimously invoked Article 21 of the Inter-American Democratic Charter to suspend Honduras following the 28 June coup d’état that overthrew President José Manuel Zelaya.

For the United States, the Monroe Doctrine and the Cold War challenge from the Soviet Union mattered as much as the sovereignty of nations in Central America and the Caribbean. The OAS did approve United States intervention in Santo Domingo in 1965, but opposed U.S. action in Nicaragua in 1979, since OAS delegates concluded that there was little threat of Soviet intervention developing from the Sandinista regime that overthrew Anastasio Somoza in that country, a view at odds with that of the U.S. government.

For a brief period, the United States seemed committed to active involvement in the Americas. In 1961, President John F. Kennedy pledged U.S. aid to help promote Latin American economic development, land reform, and social development. He promised billions of dollars to assist the efforts of Latin American governments. But, as the United States became preoccupied with the war in Vietnam, the U.S. government reduced commitments to the program, and the OAS disbanded its committee to implement the alliance in 1973.

The influence of the Organization of American States began to decline with the collapse of the former Soviet Union and the attendant end of the Cold War, as well as the involvement of major international agencies in Latin America. For the United States, matters in Latin America seemingly mattered less than peace in the Middle East, relations with the People’s Republic of China, helping Eastern Europe negotiate its post-Soviet future, and tensions on the Indian subcontinent. The International Monetary Fund and the World Bank began to play increasingly important roles in assisting the economies and governments of many of the countries of the Caribbean and Central and South America. The end of the Cold War has helped bring about a revitalization of the OAS, but future prospects hinge on dealing adequately with the inequality of power between the United States and the Latin American members, especially given concerns for democracy, human rights, security, and trade and economic prosperity.

Orientalism

The 1978 publication of *Orientalism*, a pivotal and controversial study by Edward Said, redefined a term that originally meant “scholarship that pertains to the Orient (or knowledge of Oriental languages and cultures).” Said stressed that the Western perception of the “Orient,” itself an ambiguous term, depended on creating an image of the East as the “other,” and thus facilitated its colonialization and subjugation.

Few historical terms have been as central to attempts to explain the emergence of the modern world system as *Orientalism*—the Western study (and defining) of the East. Orientalism must be understood in the context of the global history of colonialism and imperialism. An examination of Orientalism in such disciplines as the study of “Oriental” literature reveals the desire on the part of European civilization to acquire an image of its opposite: the “other.” Postcolonial critics such as Homi K. Bhabha and Gayatri Chakravorty Spivak have argued that literary texts dating from the colonial and imperial periods in particular can be exposed as claiming (Western) dominance over the rest of the world.

Edward Said and Orientalism

The American-Palestinian professor of English and comparative literature, Edward Said (1935–2003), said that literature, the arts, and politics were inseparable. His *Orientalism: Western Conceptions of the Orient* (1978), a provocative and polemical study that received praise and controversy in equal measure since its first publication, redefined Orientalism, which originally meant simply scholarship pertaining

to the Orient or knowledge of Oriental languages and cultures. For Said, Orientalism was the act, on the part of those in the West, of defining themselves by defining the “other,” the Easterner (or Oriental). He argued that this process told as much or more about the constructed self-image as about the other that the studies were theoretically attempting to define. What exactly comprises “the Orient” is not clear: for some it is the Middle East; for others it includes all of Asia. (This point can be enhanced by looking at the opulent, exotic, and erotic scene depicted in Jean-Léon Gérôme’s *The Snake Charmer* (c.1870), a detail of which graced the cover of the 1978 edition of Said’s book: Gérôme paints with nearly photographic realism in this work, but the imagery in the scene is a pastiche of Egyptian, Turkish, and Indian elements.) A further dimension comes into the discussion with Western approaches to Africa. Yet this dimension has largely been ignored so far, not least by Said himself who emphasized the congruency of the orientalist debate, including the geographical East. Marxist scholars, by contrast, have pointed to a multiplicity of problems and differences evident from many disciplines and resulting from a multidimensional relationship between knowledge and power. Knowledge, in short, was neither scientifically innocent nor politically disinterested.

Knowledge and Power

According to Said’s *Orientalism*, knowledge of the Orient produced in the West helped European colonizers maintain their subjugation and exploitation of the colonized on the one hand and their pretence of objective and detached science on the other. Knowing and naming the other, they said, preceded control

over the other. The consequence of linguistic, literary, philological and historical learning about Islam and Muslim peoples could be, for example, that it could be used as an instrument by the West to impose its worldwide superiority. Furthermore it was believed that Orientalism was also displayed in museums and in the academy as well as in biological and anthropological arguments.

In his *History of British India* (1817), the philosopher and historian James Mill (1773–1836) expressed the conviction that modernization was synonymous with Western imperial expansion, which, according to Said, also coincided with the Anglicization of the world. Thomas Babington Macaulay (1800–1859), probably the most famous nineteenth-century English historian, suggested that the evangelical and utilitarian values that were generally predominant in his age were instrumental for the reeducation of the Indian subcontinent. In the eighteenth century cosmopolitan views had been possible, indeed highly attractive for many intellectuals, who experienced an openness that had made possible comparisons between the European and Asian civilizations, encouraging the mutual reception of similarities and common ground. But in the nineteenth century a more ethnocentric attitude became the norm, as typified by opinions such as that of the philosopher G. F. W. Hegel (1770–1831), who notably called Africa a continent without history. It was out of this sense of superiority that Orientalism emerged and upon which it was based. It reflected the conviction that the peoples of the Orient (whatever that comprised) were ontologically different and represented a different type of character.

Knowledge about the Orient was thus constructed by generations of intellectuals and writers, politicians and artists. It was part of a broader imperial culture relating to the Italian political thinker Antonio Gramsci's understanding of cultural hegemony. The work of individual scholars spoke less for itself than for the uniformity of knowledge about the Orient as presented by the West. Thus nineteenth-century Western scholars were prisoners of their own academic world, unable to overcome the intellectual limits set by the methodology and the semantics of their approaches and

thus following up an ongoing monologue on a subject about which they were not objectively informed. As Said pointed out, these scholars often did not even travel to the countries about which they wrote, and therefore they could hardly claim to be well and objectively informed. The West claimed mastery of a special way of knowing called "science," a supposedly objective route to universal truths, but the omniscient attitude that went along with Western scientific inquiry was devoid of any experience of Oriental reality. The message of the Orientalist discourse was this: the East was purely receptive, a passive reactor described by adjectives such as "female," while the West was the actor of history, structuring life and judging the other. This was the relationship between the colonizer and the colonized, the ruler and the ruled.

Orientalism and Its Traditions

In the introduction to a later edition of *Orientalism*, Said claimed that in the last quarter of the twentieth century research on the Middle East, Islam, and the Arabic world had not developed much in the United States. Europe, by contrast, presented a better picture. A different perception of the East resulted from a different interest in it, whether political, economic, military, scientific, or cultural. Said suggested that the geographical proximity of Europe and the Middle East had been of great relevance for mutual cultural stimulation. He emphasized the impact of British and French writers but failed to mention German and East European scholarship.

It is striking that Said's impact on gender and literary studies, on discourse analysis and postcolonial critics, and on social studies and history has been predominantly in the English-speaking world while in Germany, for example, with its short colonial experience, Said's Orientalist thesis has had a relatively lukewarm reception. The impulses feeding *Orientalism*, however, come from a wide spectrum of intellectual sources. For obvious reasons, the period from the beginning of the direct European colonial presence and the establishment of colonial rule in the second half of the nineteenth century to the age

Jean-Léon Gérôme, *The Snake Charmer* (1880). Oil on canvas. A detail from this painting became the cover art for Said's book *Orientalism* (1978). While Gérôme painted with painstaking realism, the scene comprises elements of Egyptian, Turkish, and Indian cultures—an amalgam of the European view of the East as “the other.” Sterling and Francine Clark Art Institute.

of decolonization and political independence was of central importance for the development of Oriental scholarship.

Said believed that the Orientalist discourse experienced its first heyday in 1798, with Napoleon's invasion of Egypt. The scholar and politician C.-F. Chasseboeuf, Comte de Volney (1757–1820), who traveled in Egypt and Syria and became a prominent critic of the French campaign, nonetheless advocated forcibly changing the local government from religiously dominated despotism to republicanism. As Volney was also involved in the preservation of historical monuments, his attitude could be called an early version of *mission civilisatrice*—the civilizing mission—that manifested itself institutionally in the establishment of the French Institut d'Égypte in Cairo. The civilizing mission was an excuse for European cultural penetration of Oriental societies, legitimated by a belief in the supposedly passive character of Oriental peoples.

On the other hand, even in the earliest days there was an “Occidental” critique that shaped the understanding of how the West had projected its images of the “Other” and of how the East could reply by investigating Western cultural identity. Essentially this dialectic required not only investigation of how Orientalist and Occidental traditions were invented, but in particular against what and whom. To the same degree that Western attitudes toward

the East were formed by the colonial relationship that existed between ruler and ruled, the converse was also true: a new Occidentalism was constructed in order to draw a line between the West and the rest, to challenge this distinction and to investigate divisions within societies.

Occidentalism, however, should not be mistaken for Occidental critique of Orientalism as an academic discipline. Here, as has been pointed out, two perspectives, the religious and the Marxist, are of particular interest, especially in the Arabic world. The Palestinian scholar Abdel-Latif Tibawi is of the opinion that until quite recently most Western academics dealing with problems of the Middle East were neither adequately trained in languages and social sciences, nor sympathetic to Islamic matters. Of even greater weight was the accusation that the scholarship of Orientalists was far from objective on religious questions. Indeed, it was suggested that it had helped to develop religious hatred between Christianity, Islam, and Judaism. The Marxist argument also built on a picture of cultural confrontation, holding that Orientalism should have been overcome when former colonies asserted their political independence. It continued to exist, however, in the minds of those believing in the alleged passivity of “Orientals.” The Marxist perspective gave more attention than the religious perspective did to sociological and political concerns. Apart from recognizing the opportunity

John Frederick Lewis, *Harem Life in Constantinople* (c. 1857). Oil on canvas. The foreign exoticism of harem life fascinated Western viewers, which led Western artists to reproduce glimpses of it—in a corner of the studio.

to marginalize Eurocentric worldviews, those taking this anti-imperialist perspective saw it as advantageous for promoting academic cooperation between the peoples of Asia, Africa, and South America. The Marxist perspective, in other words, is problem oriented and takes a comparative perspective on Third World countries, as opposed to being predominantly dichotomized and discursive, as is Said's critique of existing Orientalism.

Orientalism, Said, and His Critics

Edward Said's argument in *Orientalism* is frequently criticized for lacking a sense of history. It is also considered a failing that it gave so little weight to the religious motivations of Orientalists with Christian or Jewish backgrounds who write about Muslim peoples. Yet while both history and religion were certainly crucial to the nineteenth-century understanding of Islam

and Muslims, criticism of Said's thesis have come mainly from the fields of literary criticism, cultural studies, or feminism. (Feminist scholars have taken issue with the fact that Said presented Orientalism as the domain of white male scholars and writers without paying enough attention to its female aspects.) Above all, it remains questionable whether high literature, in particular, the novel, is a suitable medium for conveying the message of imperialism on a massive scale; possibly Said the professor of literature overestimated the influence of Dickens, Kipling, Conrad, and their contemporaries.

On the other hand, Said revealed that although literary texts such as travel reports and diaries were often fictional, they purported to reflect realistically on the Orient. But can literary works that deliberately painted a fictional image of the East be accused of Orientalism? Said's critics claim that the converse was true with regard to the "Oriental discourse" of professional linguistics, for example, namely that their subject was certainly not Orientalist. Said did not discuss why in the nineteenth-century Western world it was above all professional linguistics that formed the core of the sciences of the Orient, while it was the relatively new disciplines of geography and history that exercised the greatest influence upon political decision making in colonial and imperial matters. This means that critics of Orientalism overestimate the impact of Orientalist scholars, while they underestimate the impact of those academic disciplines in which the Orientalist attitude was less visible, but probably more inherent.

Finally, critics of the concept of Orientalism have claimed that the idea of a culturally united West as suggested by Said never existed. While Said rejected the assumption that there was an entity such as "the Orient" constructed by Orientalism, he nonetheless had no reservations about speaking of a monolithic "West," a single Western civilization able to dominate the world by every means, including cognitive and cultural ones. Given the actual intercultural relationships and transfers between the continents, his critics have considered Said's model to be too strongly based on the idea of a monologue; they argue for a dialogue

Since the time of Homer every European, in what he could say about the Orient, was a racist, an imperialist, and almost totally ethnocentric. • **Edward Said (1935–2003)**

that will eventually bring the developing world back into the debate.

Notwithstanding the problematic character of many of Said's generalizations, which his critics have pointed out are often oversimplifications, it remains a particular merit of *Orientalism* that it focused and intensified research on the delicate relationship between an academic discipline and imperialism. Sensitized by *Orientalism*, scholars have reformulated questions concerning representations of the "Oriental" and the "European," intercultural communication, and the conditions under which knowledge about the other in opposition to the self can be gained.

Osman I

(c. 1258–c. 1326)

FOUNDER OF THE OTTOMAN EMPIRE

Osman established the foundations of the Muslim Ottoman Empire, one of the greatest empires in history, in the late thirteenth century, but little about his life is documented in the historical record. His immediate successors expanded the Ottoman state far beyond the small part of Anatolia that Osman ruled.

Scholars know more from legend about Osman, the ruler who “gave” his name to the Ottoman Empire (*Osman* is ‘*Uthman* in Arabic, hence Othman and Ottoman), than from historical evidence. No one knows, for instance, when precisely he was born or began to rule. But it is certain that the major events of his lifetime occurred in the early fourteenth century.

The son of Ertugrul, Osman led a small emirate in Anatolia (modern Turkey). It was but one of numerous Turkic emirates in the region. Originally, Osman and his father had entered the service of the Seljuks with a small following, fleeing westward away from the Mongols. After his father’s death, Osman’s emirate increased in power, often at the expense of the Seljuks, and Osman expanded his territory in order to gain more pasturage for his nomadic troops. He grew sufficiently strong that his forces successfully repulsed a few attempts by the Mongols to impose their authority over him.

From coins dating from the era, it is known that Osman was an independent ruler by 1281 and that he fought with Byzantine forces on numerous occasions, usually emerging as the victor. His base of operations was in the Sakarya River valley in northwestern Anatolia. However, details from the contemporary sources are very sketchy, and most

Portrait of Osman I, founder of the Ottoman Empire.

knowledge of his activities seem to be based in tradition rather than any historical record. Nonetheless, it is known that his forces operated on the frontier of the Islamic world and that of the Byzantines. Osman defeated the Byzantines near Nikomedia (Izmit) and also at Katoikia. It is unclear when these battles occurred; the contemporary chronicler, Pachymeres, however, places them before 1307. Although Osman enjoyed success against

the Byzantines, it was not uniform as he failed to take Bursa and Iznik.

Osman's role in world history is greater than his actions during his lifetime would indicate. He established the foundations for one of the greatest Muslim empires, and indeed, greatest empires of any kind, in history. His immediate successors continued to expand the nascent Ottoman state far beyond the small part of Anatolia that Osman ruled. While it is uncertain how much of a factor religion actually played in the wars between Osman and the Byzantines, it became part of Ottoman tradition that the Ottomans started off as Muslim warriors who lived on the frontier specifically to do battle with nonbelievers.

Ottoman Empire

The Ottoman Empire (c. 1300–1922) is among the most durable and successful empires in world history. It spanned the late medieval, early modern, and modern periods and, at its peak, held possessions on the continents of Europe, Asia, and Africa. Although officially an Islamic state for nearly all its history, the Ottoman state ruled over primarily Christian subjects until its final half-century.

The Ottoman Empire (c. 1300–1922) first emerged in the northwest corner of Anatolia, then in the midst of its transformation from a Greek-speaking Christian to a Turkish-speaking Muslim cultural zone. Indeed, the formation of the Ottoman state accompanied and completed this transformation. The Ottoman state achieved world-empire status in 1453, when it conquered Byzantine Constantinople. Between the fourteenth and seventeenth centuries, the Ottoman Empire was among the most powerful states in the Mediterranean and European regions. Indeed, for a time it may have surpassed all other states in the world except Ming dynasty China (1368–1644) in political, military, and economic power.

International Political Developments

The Ottoman transition from principality to a world empire, in common with imperial achievements elsewhere in the globe, derived from a complex mix of factors that included geography, the proximity of weak enemies, and luck. But we must also give substantial credit to Ottoman policies and achievements. After

all, there were many small states and principalities struggling for supremacy in Anatolia following the migrations of Turkish peoples from Central Asia. The Ottoman family emerged on the Byzantine borderlands not far from Constantinople (now Istanbul). The dynasty and its supporters employed pragmatic statecraft and methods of conquest. They rewarded the human material at hand and cared little if it was Christian or Muslim or Greek, Bulgarian, Serb, or Turkish. Thus, on these early battlefields, the Ottoman dynasty commonly led troops that were a combination of both Muslim and Christian warriors. These pragmatic policies also included an exceptional openness to innovation, including military technology. Until sometime during the seventeenth century, the Ottomans typically enjoyed tactical battlefield superiority. Overall, openness and innovation go far in explaining why the Ottoman principality emerged as a world power. Like Rome, the Ottoman emergence to empire status was not overnight but built on a steady record of achievement and determination. The Ottoman Empire offered a durable example of state building in its combination of military power and an eye to justice and toleration of differences among its subjects.

During the seventeenth century, however, Ottoman preeminence slipped away. Just as explanations of the rise of empires remains elusive, so too are those regarding their decline. In the Ottoman case, it seems clear that factors at work well beyond its frontiers played a large role in the deterioration of the Ottoman international position. There is no doubt that the rise of capitalism and industrialism in Europe, western Europe's conquest of the New World, and

its monopoly access to American wealth, are keys in understanding the mounting imbalance between Ottoman and European military and economic power. By the beginning of the nineteenth century, the Ottoman Empire had become a second-class economic, military, and political power, and it shared a common fate with the entire non-European world save Japan after around 1850. Economically, the wealth gap between Ottoman subjects and residents in most west European states widened. Politically, the Ottomans became part of the “Concert of Europe” at the mid-nineteenth century point but remained subordinate to the Great Powers such as Britain, France and the emergent Germany.

Internationally, on its western and northern fronts, the state encountered increasingly powerful enemies that had been enriched by New World wealth and could better bear the mounting costs of outfitting and maintaining armies in the field; expansion finally ground to a halt in the late seventeenth century. Innovation diminished as entrenched bureaucrats and statesmen acted to preserve positions for their

children and closed entry to innovative newcomers. A catastrophic military failure at Vienna in 1683 was followed by some victories but mainly defeats during the subsequent one hundred years.

During the nineteenth century, there was an important reversal of fortunes as a series of successful reform programs measurably strengthened both the Ottoman state and its military. The size of the central bureaucracy increased substantially as the state increasingly sought to more closely control the lives of its subjects/citizens. Previously, the early modern Ottoman state, like its contemporaries across the globe, mainly had collected taxes and maintained order. In its more modern guise, the Ottoman and other states now took responsibility for the health, education, and welfare of its subjects and sought to bring government into every sphere of life. In this attempt, the Ottoman state enjoyed many successes during the nineteenth century and was vastly stronger in 1914 than it had been around 1800. Despite this impressive record, the Ottoman Empire was defeated in World War I and

Our strength lies in our intensive attacks and our barbarity . . . After all, who today remembers the genocide of the Armenians?" • Adolf Hitler (1889–1945)

partitioned by the Great Powers, notably Great Britain and France. Ottoman successor states include today's Albania, Bosnia, Bulgaria, Egypt, Greece, Iraq, Israel, Lebanon, Montenegro, Romania, Saudi Arabia, Serbia, Syria, Turkey, and other states in the Balkans, the Arab world, North Africa and the north shore of the Black Sea.

Domestic Political Developments

From the perspective of domestic developments, the Ottoman state underwent continuous change over the centuries. The Ottoman ruler, the sultan, began as one among equals but between the conquest of Constantinople in 1453 and the later sixteenth century, the Ottoman sultans ruled as autocrats. Thereafter, until around 1800, other members of the imperial household, often cooperating with provincial notables, controlled the state. During the nineteenth century, bureaucrats and sultans vied for dominance, with the former in charge in the middle of the century and the sultan during its first and fourth quarters. Overall, sultans presided over the imperial system for all of Ottoman history but actually, personally, ruled only for portions of the fifteenth, sixteenth, and nineteenth centuries. It seems important to stress that the principle of sultanic rule by the Ottoman family was hardly ever challenged through the long centuries of the empire's existence. Unlike in the Chinese case, there was no Mandate of Heaven that could move to a new family and justify the overthrow of a dynasty.

Over the centuries, political power nearly always resided in the imperial center and, depending on the particular period, extended into the provinces either through direct military and political instruments or indirectly through fiscal means. The central regime exerted its military, fiscal, and political authority through mechanisms that evolved continuously. Thus, there was not a single Ottoman system or method of rule, except one of flexibility, adaptability, and change.

During the early centuries, the *timar* system was the financial basis of the cavalymen, who fought

with bows and arrows. Under this system, the state granted to each cavalryman (and others who served the state) the revenues from a piece of land but not the land itself, in a quantity sufficient to maintain the cavalryman and his horse. He did not actually control the land, but only the taxes deriving from it. Peasants worked the land and paid taxes that supported the *timar* cavalryman both on campaign and at home. This *timar* system was at the center of Ottoman fiscal and military affairs only for the earlier portion of Ottoman history, perhaps only during the fourteenth, fifteenth, and part of the sixteenth centuries. Hardly had the state developed the *timar* system when the regime began to discard the cavalymen and, along with them, their *timar* financial underpinnings. The *timar* system nominally endured until the nineteenth century. Infantrymen bearing firearms became increasingly important. As they did, the famed Janissary Corps ceased to be a gun-wielding praetorian elite and developed into a firearm-bearing infantry of massive size. Support of these full-time soldiers required vast amounts of cash. Therefore, tax farming, which provided cash revenues, steadily replaced the *timar* system, which received taxes mainly in kind, as the major fiscal instrument. By 1700, lifetime tax farms began to become commonplace and dominated the fiscal system in the later part of that century. Despite these changes, Ottoman military forces lost out in the arms race by the end of the seventeenth century because tax revenues from agricultural pursuits could not match European revenues derived from a combination of colonialism, mounting world trade and the burgeoning domestic economy. During the eighteenth century the makeup of Ottoman military forces continued to change: the Janissary infantry and the *timar* cavalry continued to exist in name but gave way in importance to the troops of provincial notables and the forces of the Crimean khanate, a vassal state. The changes during the nineteenth century were more radical: universal manhood conscription controlled by the central state slowly developed. Lifetime tax farms were abandoned, but tax farming nonetheless continued, a measure of the continued

Ottoman troops, 1914, Gaza. The empire was defeated in World War I and partitioned by the Great Powers, notably Great Britain and France.

cooperation between the central elites and local notables.

Until the later nineteenth century, perhaps surprisingly, most Ottoman subjects were Christian. But, thanks to territorial losses in the mainly Christian Balkan provinces, Muslims became the majority element in the empire by the third quarter of the century. But regardless of whether they were Muslim, Christian, or Jewish, all subjects fell under the jurisdiction of both religious and secular law. In the eyes of the state, Muslims enjoyed a legal position superior to Christians and Jews—however, these latter groups possessed guaranteed legal rights and status. For these rights and legal protections, non-Muslims paid a special tax. Otherwise, all the communities were subjects to the same taxes. The Ottoman state determined who administered the laws governing a community, whether that of the Muslim, Christian, or Jewish community or of the imperial state. The sultan

and his agents determined the judges in the respective communities either directly or by appointing those who in turned named the judges. Theoretically, the religious law of the respective group prevailed in the particular Muslim, Jewish, or Christian community. But, practically speaking, the Muslim courts very often were used by subjects of all religions. There were several reasons for this, including the quality of the justice that the judge administered and the fact that it was understood that rulings from such courts might well have greater weight than those from Christian or Jewish sources. In addition to this religious law, the state routinely passed its own, secular ordinances (always with the assertion that such rules adhered to Islamic principles). In the nineteenth century, when a flood of ordinances and regulations marked the presence of an expanding bureaucratic state, even the lip service frequently fell away in favor of scientific management. Moreover, as part of its nineteenth-

Silk-reeling workers, Bursa area, 1892. Spinning operations, staffed largely with female laborers, emerged as an important new export industry for the empire.

century reform agenda, the state sought to replace the religious courts with secular ones, an effort strongly opposed by many Ottoman Christian leaders, who feared a loss of influence, and their patrons among the European states.

Ottoman Economy

The Ottoman Empire remained populated mainly by cultivators who raised a wide variety of crops for subsistence and sale. Many not only farmed but also manufactured handmade textiles and other products, again both for personal use and the market. Cereals always topped the list of crops that they grew. Following ancient regional precedents, the sultan theoretically owned the vast majority of

land and allowed others to grow crops and raise animals. In practice, generally, these land users enjoyed security of tenure and stayed on the land for generations. Sharecropping was widespread, and during the nineteenth century, at least, was the source of most crops that were sold in the marketplace. Most cultivators were small landholders; large estates were comparatively unusual. Slave labor was common for domestic work but very rare in agriculture. Commercialization of agriculture enjoyed considerable development in the eighteenth and nineteenth centuries in order to meet mounting foreign demand and, in the latter period, the needs of an increasing number of Ottoman city dwellers. Ottoman manufacturing, for its part, remained largely the domain of small-scale hand producers,

although there was some mechanization in the late period. Ottoman manufacturers lost most of their existing foreign markets between 1700 and 1800 because of protectionist policies overseas and because of the increasing efficiency of European manufacturers, itself based on a combination of the more ruthless exploitation of labor and mounting mechanization. During the nineteenth century, however, rug making and silk spinning operations, staffed largely with female labor working outside the home, emerged as the most important of the new export industries. Throughout, Ottoman manufacturers retained the important domestic market for their wares. Important technological breakthroughs occurred in transport and communication during the second half of the nineteenth century. Steam replaced sail on the seas. Railroads emerged, but these were mainly in the Balkan provinces that later were lost. Additionally, a fairly thick network of telegraph lines connected most towns and cities by the later 1800s.

Ethnic and Religious Group Relations

The issue of the state's treatment of its non-Muslim subjects and the entire question of relations among the various ethnic and religious communities remains a hotly debated subject today, among both politicians and scholars. Many residents of Ottoman successor states, especially those in the Balkans, look back on the "Ottoman yoke," which they finally shook off. They remember the injustices and forget the toleration of Ottoman rule. Their frequent detestation of the Ottoman era is a sentiment often deriving from nation-building mythologies put in place after the end of Ottoman rule rather than the actual experiences with that administration. As mentioned at the start, until the later nineteenth century, the majority of Ottoman subjects were Christians of one kind or another although the state's official religion was Islam. Here, indeed, is a key to Ottoman longevity—the Ottoman state nearly always functioned as a multinational, multireligious entity

that did not seek to impose religion or define itself in terms of the ethnicity of its subjects. The durability of the empire can be attributed to its toleration of difference among its subjects. And, as long as subjects paid their taxes and rendered obedience, the state protected the expression of these differences. For much of the Ottoman era, it is quite likely that minorities within the Ottoman realms received better treatment than they did in Europe or China. While the Christian and Jewish minorities were second to Muslims, they did have guaranteed protection under Ottoman law, legal assurances that religious minorities in Europe did not possess in Europe. As Enlightenment notions of equality developed during the eighteenth century and later, however, these Ottoman methods seemed less attractive. While, during some years of the final Ottoman era, there were atrocities, these should be understood in the context of the generally admirable record of intercommunal relations over the six-hundred-year life span of the empire. Proof of Ottoman toleration can be found in ethnic and religious maps of the former Ottoman lands. If the Ottoman state had pursued policies of stamping out difference, how can we explain the rich diversity of ethnicities and religions that prevails in nearly all of these present-day countries?

Pacific, Settlement of

Archaeological evidence shows that humans inhabited most islands of the Pacific by about 1000 CE. The settlement of these islands required longer ocean passages than any voyages made prior to European exploration in the fifteenth century. Long-distance seafaring, patterns of island colonization, and the impact of people on long-isolated and fragile environments are issues significant and relevant to world history.

When Captain James Cook discovered Christmas Island, at the very center of the Pacific Ocean, in 1777, he wrote that there was no trace of any people having been there before him. He was mistaken, for his men had seen some rats, which must have been introduced by humans, and subsequent research shows that Polynesians had colonized Christmas Island five hundred years before its European discovery. In fact, archaeological evidence shows that most of the approximately 1,500 habitable Pacific islands had been settled by about 1000 CE in a series of migrations that required the longest ocean passages prior to the voyages of European exploration in the fifteenth century. The development of long-distance seafaring, the consequent pattern of island colonization, and the impact of people on long-isolated and fragile environments are issues of significance to world history.

Stretching across one-third of the earth's surface, the Pacific Ocean is vast, varied, and scattered, with perhaps 25,000 islands of all types and sizes, most of them in a wide tropical belt that extends southeast from Indonesia to Easter Island. They were settled in two broad phases of migration. The large islands of Southeast Asia, Australia, New Guinea, and the Solomons constitute "Near Oceania," and they were

first settled during the Late Pleistocene. The generally small islands of Micronesia, eastern Melanesia (Vanuatu, New Caledonia, Fiji), and Polynesia (all the islands in the triangle with vertices at Hawaii, Easter Island, and New Zealand), are known collectively as "Remote Oceania" and were settled first during the Late Holocene.

Pleistocene Migration and Holocene Developments

As sea levels were 120 meters lower in 25,000 BCE, today's Southeast Asian islands as far east as Bali and Borneo, and also Taiwan and Japan, were then attached by dry land to the Asian mainland and inhabited by large placental mammals, including elephants, deer, pigs, and people. Australia and New Guinea, however, formed a separate landmass, known as Sahul, which supported an ancient biota characterized by its marsupial mammals. Between them lay the island-studded sea of the mixed-biotic province of Wallacea. It is possible that some islands, notably Flores, had been reached by the Javan population of *Homo erectus*, which dates to 1.0–1.8 million years ago, but archaeological data suggest initial colonization of Sulawesi, Maluku, Timor, and the Philippines in the period 50,000–35,000 BCE. By 45,000 BCE, Sahul had also been colonized. The migrant populations were undoubtedly *Homo sapiens*, and their modern descendants, such as Australian aboriginals and Highland New Guineans, retain genetic markers that link them to the early diaspora of our species from its African homeland.

Pleistocene maritime technology is entirely unknown. However, as *Homo erectus* was tied almost

entirely to dry land migration, even the modest dispersal of early *Homo sapiens* across Wallacea appears significant by contrast. Natural rafts of giant-bamboo clumps and other materials are quite common in the region and may have been used more by our species than earlier hominids to cross estuaries and lagoons, so that over many thousands of years the chance movement of small breeding units over distances of up to 170 kilometers, as was required to reach Australia, seems possible. At the other extreme from this proposition is the view that invention of formal watercraft, such as canoes and shaped rafts, and even of sailing technology, can be attributed to Pleistocene populations. There is evidence that not only people, but also some useful animals, such as possums and small wallabies, were introduced to new islands as early as 35,000 BCE, and that obsidian tools were being taken from New Britain to New Ireland by 20,000 BCE. Whatever the case, it is important to observe that the maximum achieved passage length remained at about 200 kilometers throughout the Late Pleistocene and Early Holocene. Seafaring may have become more frequent with time, but it did not become more extensive or efficient until the Late Holocene.

By 9,000–6000 BCE, rising sea levels had divided the Sahul landmass into New Guinea, Australia, and Tasmania, and the isolated populations followed different cultural trajectories thereafter, within

exclusively foraging societies in the latter two regions. In New Guinea, however, there is evidence of the early development of agriculture. Research at the Kuk site, at 1,600 meters altitude in the Wahgi Valley, shows that by the Early Holocene (c. 8,000 BCE), there was systematic exploitation of pandanus (screw pine) and banana, and by 5000 BCE, formal garden mounds and drainage ditches were being constructed. These were probably for cultivation of taro, sugarcane, and bananas, all of which seem to have been domesticated in New Guinea, along with yams and breadfruit.

By the Late Holocene, around 2000 BCE, gardening was probably widespread in New Guinea, and possibly the Solomon Islands, and both the existence of ground-stone adzes suitable for carpentry and evidence of the frequent movement of obsidian around the New Guinea islands indicate that canoes or other ocean-going watercraft existed. In the event, however, it was external influences that were instrumental in propelling the Late Holocene phase of maritime migration.

Settlement in Remote Oceania

Archaeological evidence shows that about 1300–1200 BCE, the older aceramic cultures of the New Guinea islands, notably of the Bismarcks, were largely replaced by a material culture that included pottery,

An engraving from the *Collection of 52 Maps and 133 Plates to Illustrate Captain [James] Cook's Voyages to the South Pacific and North West Coast of America*, published in Holland, 1793–1794.

polished stone adzes and chisels, slate and shell tools, and distinctive ornaments and fishhooks. While at least some of these elements have a long history in the New Guinea region, including shell adzes, shell beads, and simple fishhooks, ceramics were new, and the distinctive red-slipped, dentate-stamped types can be traced to earlier sites in Southeast Asia. In turn, these represent the expansion, after about 2500 BCE, of a Neolithic culture that had its origins around 5000 BCE in South China. This involved the cultivation of rice and millet and the husbandry of pigs, dogs, and chickens.

Cereal cultivation never reached the New Guinea region or anywhere else in Oceania, but the domestic animals and ceramic culture did, and they were probably associated with gardening of taro, bananas, breadfruit, and other crops. Linguistic and genetic data show that this was not just a case of cultural diffusion. There was also substantial migration. People of Southeast Asian ancestry moved into coastal New Guinea and on to its smaller islands and intermarried with the resident people. The immigrant languages of the Austronesian family prevailed, and it was this culturally mixed population that began the second great phase of Pacific settlement.

Between 1000 and 800 BCE, there was a rapid migration from the New Guinea islands southeast to Vanuatu and New Caledonia and east to Fiji, Tonga, and Samoa. Taken from the name of an early site in New Caledonia, this is known as Lapita culture. At some point, not necessarily at the beginning, it

introduced the pig, dog, and chicken, and almost certainly also the cultivation of root and tree crops, into the remote Pacific islands. As obsidian from New Britain is found as far east as Fiji and decorative styles on Lapita pottery changed synchronously, there was either repeated migration or some degree of interaction throughout the region. Lapita was contemporaneous with movement of a similar ceramic culture into western Micronesia, and both represent the beginning of long-distance seafaring in the Pacific. Equally importantly, from Lapita onward eastward migration in Remote Oceania was into islands where hitherto a few species of bats were the highest form of terrestrial mammalian life.

Seafaring and Colonization

A sudden and sixfold increase (to 1,200 kilometers) in voyaging range at about 1000 BCE indicates the advent in the Pacific of the sail, first recorded in China and Egypt by 3000 BCE, and probably also of shaped paddles used for both propulsion and steering, and the development, with vessel controllability, of rudimentary stellar navigation. The evolution of voyaging technology thereafter has been one of the most important issues in the settlement history of Remote Oceania. The traditional view, espoused by the historian Peter Buck, was that early colonists used large, fast, double-hulled canoes that were capable of sailing into the prevailing southeast trade winds. Based on that assumption, modern voyaging

Nine men on an outrigger canoe, near coast of Fiji.
Photo by William Henry Jackson.

researchers, such as Ben Finney, have worked with indigenous seafarers to build substantial double-hulled canoes, notably *Hokule'a*, and sail them around the Pacific to demonstrate the voyaging skills of ancient Polynesians. The performance data gained in these practical experiments were then used in computer simulations, which suggested probable patterns of early maritime migration. The conclusions of this neotraditional research were that voyaging capabilities were sufficiently sophisticated that no part of Oceania remained beyond reach, so that the overall pattern of colonization was broadly continuous from west to east; Lapita colonization reached as far east as Samoa at about 900 BCE, to the Cook Islands in East Polynesia by 500 BCE or earlier, and then throughout East Polynesia by 500 CE.

Recent chronological research in East Polynesia has cast doubt on this hypothesis. Key archaeological sites have provided significantly younger ages than existed in earlier data. For instance, the important Marquesan site—Ha'atuatua, Hane, and Anapua—once dated to about 1 CE are now dated no earlier than about 900 CE, and there are similar results from throughout East Polynesia. Consequently, the pattern of settlement history in Remote Oceania appears episodic rather than continuous, as follows:

1. a very rapid dispersal 1000–800 BCE of red-slipped pottery-using cultures, especially Lapita, into western Micronesia and from New Guinea to West Polynesia;
2. expansion into central Micronesia, probably from the Santa Cruz islands, and colonization of some islands marginal to the eastern Lapita expansion (Niue Pukapuka and Rotuma), about 200 BCE;
3. rapid, aceramic dispersal from West Polynesia into and through East Polynesia at 900–1100 CE; and
4. colonization around 800–600 CE of South Polynesia (New Zealand and outlying archipelagos).

Sailing Downwind

The punctuated pattern of settlement suggests that the assumed sophistication of seafaring in Remote Oceania needs to be reconsidered. So also do linguistic data that show that the term for “double canoe” did not occur before the development of Central Pacific languages, that is after the Lapita expansion, and that there were no terms for either “fixed mast” or “standing rigging.” Early migrations probably used outrigger canoes. In the western Pacific and Southeast Asia, these canoes had lateen rigs historically, but those may not have been introduced to Remote Oceania until about 1200 CE, through the influence of expanding Arabian seafaring technology. In the central and eastern Pacific, Oceanic spritsails were dominant historically, and the early form of these, found in New Zealand and probably the Marquesas, had no fixed mast or rigging. It consisted of two spars, with a triangular sail, apex down, and it was held up only by

wind pressure against sheets held aft. Canoes using it sailed downwind because the absence of side-stays meant that winds on the beam would push the rig overboard. Since historical observations show that more complex rigs, including the lateen sail with its fixed mast, halyards, and balance boards, were only reaching the Central Pacific in the seventeenth and eighteenth centuries, long after the colonization of East and South Polynesia, it can be hypothesized that the New Zealand rig was used throughout Remote Oceanic colonization.

Although quite simple, this rig could be repaired at sea and set in high- or low-aspect shapes. It avoided the massive stresses on gear, especially on fragile pandanus sails of windward sailing, and it could be demounted instantly in high winds or squalls. But sailing with this rig must have been relatively slow and highly dependent on fair winds. The question then arises of how the settlement of Remote Oceania was achieved by vessels that could not sail into the prevailing trade winds.

Westerly winds occur briefly but frequently so they cannot explain the long pauses in the colonizing sequence. However, there was also long-term variation in the frequency of westerly winds of El Niño origin. Proxy measures of the frequency and intensity of El Niño conditions, including long-term records of loess production in China, of changes in ocean circulation, and of sediment deposition in lakes, indicate that El Niño frequencies were unusually high about 3000 BCE, 1400–500 BCE, 400–900 CE, and 1100–1700 CE. Dispersal out of Southeast Asia, the Lapita expansion, and movement into East Polynesia approximate this pattern. They were all largely west-to-east movements. East-to-west movements into Central Micronesia and to South Polynesia occurred at intervening periods during the “normal” pattern of trade wind dominance. In summary, migration in Remote Oceania may have been restricted to downwind sailing at slow average speeds on long passages. Successful voyaging would have been significantly more difficult, with much lower rates of success than is envisaged in traditionalist and neotraditionalist hypotheses. It was probably undertaken uncommonly at times when

This photograph taken in the 1920s by Edward A. Salisbury shows warriors and their canoe on the beach at Vella Lavella, one of the Solomon Islands. The sides of the canoes were beautifully inlaid with pearl shells in intricate designs. Library of Congress.

winds were predominantly adverse, but occasional significant episodes of frequent wind reversals would have provided conditions that enhanced the probability of colonizing success toward the east.

Faunal Devastation

When colonists reached uninhabited islands, they broached ancient and fragile ecosystems with devastating results. The scale of the assault was realized as early as 1843 when remains of extinct giant birds (moa) were found in Maori middens. Evidence of anthropogenic change has continued to accumulate ever since. Extinction of terrestrial vertebrates is widely documented. Large flightless birds became extinct in Pleistocene New Ireland. The giant megapode, or brush fowl; a land crocodile, *Mekosuchus inexpectatus*; and a giant horned tortoise disappeared in New Caledonia, and the giant iguana and megapode in Tonga. Recent research shows that numerous species disappeared with the arrival of people in Fiji. These

included another land crocodile, *Volia athollander-soni*; a giant iguana and tortoise; a giant frog; two large megapode species; another giant megapode, *Megavitiornis altirostris*; and a giant flightless pigeon, similar to the dodo. In New Zealand nearly forty species of birds, including thirteen species of moas, disappeared. This represents a 50 percent decline in the number of bird taxa (taxonomic groups) breeding on the mainland, and similar losses were sustained on Hawaii and elsewhere in East Polynesia, from the central archipelagos to the margins. Extinctions occurred rapidly, although perhaps not as quickly on large islands as the fifty years after human colonization preferred for moa extinction in one scenario. As well as extinction, there was also depletion and range contraction among other taxa. Some seal species occur in the earliest archaeological sites in subtropical Polynesia, but by the eighteenth century, they were found only in New Zealand, where their breeding ranges had contracted almost to the subantarctic under hunting pressure.

These data show that faunal collapse in Remote Oceania was rapid and early. The typical pattern is for remains of extinct taxa to be found in sites that date to the initial century or two of human settlement and thereafter to be absent. Extinction, at least among the larger-bodied taxa, was density-independent, that is, small human populations of widely varying density distribution could still devastate indigenous faunas very quickly. In addition, it is now clear that the process was virtually universal. So much so, that David Steadman estimates a loss of 8,000 species or populations within Oceania generally.

Deforestation

Profound changes also occurred in vegetation patterns. Forests retreated with the advent of people who wanted to create agricultural land and whose pigs, chickens, and rats foraged for seeds on the forest floor. In New Caledonia there was some loss of diversity in forest trees after 1000 BCE, and massive deforestation began by 500 BCE. On Viti Levu, the main island of Fiji, substantial deforestation began about 100 BCE

but earlier on the smaller islands. These data suggest that in the Lapita region, settled by 1000 BCE, there was relatively little initial impact on the landscape, but that massive changes in sediment distribution and vegetation patterns developed as population density increased and settlement expanded inland. Sediment from the hills was eroded into the valleys and redeposited around the coasts, increasing opportunities for agricultural development.

The pattern in the eastern area is less clear, largely because of uncertainty about the timing of initial human colonization. Aceramic East Polynesian archaeology lacks any horizon marker of initial colonization comparable to Lapita pottery. Apparently, anthropogenic landscape changes have been dated to 1500 BCE in Mangaia, Cook Islands, and to 500 CE in New Zealand, Easter Island, and the Societies, using samples from lake sediment cores, but the results are contentious. Recent research in New Zealand shows that lake sediments are often contaminated by in-washing of old soil carbon and that radiocarbon dates are therefore too old.

Landscape change in Remote Oceania appears, therefore, to divide into two patterns. In the large western islands, it was often slow to start and took up to a millennium to assume major proportions. This seems to be a density-dependent pattern that was tracking the progressive expansion of agriculture. In the eastern islands, there was a stronger early impact, probably reflecting the small size of many islands, their very steep slopes and relatively fragile soils, and increased climatic volatility in the second millennium CE.

Island Settlement

Settlement of the Pacific occurred in a series of maritime migrations that began during the Pleistocene and accelerated in frequency and range during the Late Holocene. The movement into and across Remote Oceania probably reflected improvements in maritime technology, the impetus of favorable climatic episodes for sailing, and the utility of agriculture for sustained island settlement. Fragile island environments were altered profoundly by human colonization. Yet, if

extinction on Oceanic islands was catastrophic for biological diversity, exploitation of the abundant and naïve fauna was also an optimal strategy of initial human survival on islands. Such an easy food supply allowed small colonizing populations to grow rapidly and avoid their own possible extinction as quickly as possible. Likewise, substantial deforestation and redeposition of upland sediments opened up the possibility of long-term demographic success by intensive agriculture. Significant anthropogenic environmental modification, in other words, underwrote the successful settlement of most Pacific islands.

Paleoanthropology

The broad area of science known as paleoanthropology, which seeks to understand the biological and cultural evolution of *Homo sapiens*, takes a largely multidisciplinary approach, with numerous experts—from geochronologists to archeologists and a host of others—involved in field research and the study of the fossil record.

Paleoanthropology is the broad field of science devoted to understanding the biological and cultural evolution of our own species, *Homo sapiens*, and of the zoological family Hominidae to which it belongs. (Hominidae is the family of primates that contains the living *Homo sapiens* and its close fossil relatives—those that are not more closely related by descent to the living great apes: the chimpanzees, bonobos, gorillas, and orangutans.) Central to the practice of paleoanthropology are paleontologists, scientists who study the fossil record that comprises the direct biological evidence of humanity's past; but the field is fleshed out by scientists of many different kinds, including stratigraphers, geochronologists, taphonomists, functional and comparative anatomists, systematists, molecular and population geneticists, archaeologists, evolutionary biologists of various kinds, and a host of others. The notion of paleoanthropology as an essentially collaborative area of science dates back to the early 1960s, when Louis Leakey (earlier in his career the very exemplar of the traditional “lone paleontologist”) and his wife Mary brought together specialists of various kinds to investigate the hominid-bearing deposits of Olduvai Gorge, in Tanzania. Clark Howell, then of the University of Chicago, soon thereafter made the multidisciplinary approach definitive in his explorations of the fossil-rich sediments of the Omo

basin in southern Ethiopia. Since that time virtually all intensive human evolutionary field investigations have included a diversity of experts and have involved collaborations with many outside specialists.

The Nature of the Evidence

The archive of human biological evolution is the fossil record. Fossils consist of the remains of dead creatures that have been preserved in the accumulating geological record. Almost invariably, such remains consist of bones and teeth, since these are the hardest elements of the body and best resist decay and other forms of destruction. The destructive processes themselves are the specialty of taphonomists, who study how remains are scattered and broken postmortem, and how fossil assemblages are accumulated. Fossils of land creatures are preserved within the sedimentary rocks that result from the deposition of eroded particles, principally by water in lakes and rivers. Such sediments are laid down in sequences within which later deposits overlie earlier ones, a process that is reconstructed by the geologists known as stratigraphers. The place of fossils in a rock sequence can determine their *relative* age (older than this, younger than that), but the determination of *absolute* ages (in years) is the province of geochronologists. In their efforts to quantify the time that has elapsed since a particular event (the cooling at the surface of a lava flow, for instance), geochronologists most frequently take advantage of the fact that unstable, “radioactive,” forms of elements contained in rocks “decay” to stable states at known and constant rates. For earlier periods, volcanic rocks (which may be interlayered in sedimentary sequences, and hence give an estimate of the age of fossil-bearing sediments above and below

Front and side views of a Neanderthal skeleton. G. J. Sawyer and Blaine Maley reconstructed this composite skeleton in 2005, using casts of bones from five different sites in four countries.

them) are favorite objects of geochemical dating; in more recent times, actual fossils (e.g., by radiocarbon) or sometimes even artifacts (e.g., by thermoluminescence) can often be assigned dates in years.

The fossils themselves provide information of many kinds. First, they tell us about the variety of hominids that existed in the past. Based on their anatomical similarities and differences, paleontologists first classify fossils into species, which are both the basic *kinds* of organisms and the building blocks of ecosystems. Elementary as it may sound, the sorting of fossils into species is one of the most difficult processes in paleoanthropology, and one of the most contentious. In recent years new methods such as scanning electron microscopy and computerized tomography have helped to enlarge the range of morphologies that can be brought to bear on such problems. Once species are recognized, their genealogical relationships (those due to ancestry and descent) may be inferred. Again, such inferences are normally based on their morphologies and are similarly subject to a variety of

algorithms and approaches. Over the past few decades molecular comparisons among extant species have helped solidify our notions of the relationships among extant species, and hence of the framework within which hominid fossils have to be fitted. In the hominid arena, molecular evidence has served to substantiate the species difference between *Homo sapiens* and *Homo neanderthalensis*, following the recent success of molecular geneticists in extracting short sections of mitochondrial DNA from fossils of the latter.

Further anatomical scrutiny can reveal a great deal about how extinct species may have lived. Particularly when functional comparisons can be made with the structures of extant forms whose behaviors are known, such study allows tentative reconstruction of the anatomically limited (in the hominid case, most importantly locomotor) behaviors of the species concerned. In rare cases, such as the famous 3.5-million-year-old footprints preserved at Tanzania's Laetoli that directly document upright bipedalism at that great remove in time, the inferences made from bony anatomy may be independently confirmed. Our understanding of what our predecessors ate is enhanced by analyses of teeth and of how they wear, and the analysis of stable isotope ratios in fossil bone can further augment our understanding of ancient diets. Further, the examination of associated fossil faunas and floras, and of the geological evidence for the circumstances in which sediments enclosing particular fossils were deposited, can reveal a great deal about the environments in which the creatures of interest had lived and behaved.

In the hominid case, our knowledge of ancient behaviors is vastly enhanced by the archaeological record, which begins around 2.5 million years ago with the invention of the first stone tools. Archaeology, sometimes defined as "the study of ancient garbage," focuses upon the traces—of any and all kinds—of their activities left behind by ancient humans. It is not confined simply to the study of ancient artifacts, but also extends to the ways in which those artifacts were accumulated at particular sites, and to how such sites are located within the landscapes in which they are found. By combining analyses at all these levels, much can be determined about how now-extinct humans

interacted with the environment around them and to a certain extent with each other, though it has to be admitted that even a rich archaeological record is but an indirect reflection of the complex social, economic, and material lives that were led by earlier hominids.

The Human Evolutionary Record

The reconstruction of the human evolutionary past has been greatly influenced by views of the evolutionary process itself. In the mid-twentieth century, most Anglophone paleoanthropologists fell under the sway of the “Evolutionary Synthesis,” a view of the evolutionary process that ultimately ascribed virtually all evolutionary phenomena to gradual generation-by-generation change of gene frequencies in populations, under the guiding hand of natural selection (whereby in each generation those individuals with favorable heritable adaptations reproduce more successfully than those less favorably endowed). This perspective led to an essentially linear view of human evolution, which was seen as involving a slow, dogged slog from primitiveness to our current burnished perfection.

Subsequently, an enlarging hominid fossil record forced the realization that the evolutionary process is more complicated than this, and is subject to a host of external influences, many of which are entirely random with respect to adaptation. The resulting picture of the hominid record is one of diversity, of evolutionary experimentation whereby many hominid species have emerged and done battle in the ecological arena, trying out the many ways there evidently are to be hominid. The story of our family is one of many species originations and many species extinctions. It may seem natural to us today, since this is what we are familiar with, that *Homo sapiens* is the lone hominid in the world; but in fact it is a highly atypical situation, and one that strongly hints that there is something very unusual indeed about our species.

The First Upright Biped

The earliest fossils that have been claimed to lie somewhere in our ancestry, but not in that of the apes as well, come from African sites in the period between 7–6

and 4.4 million years ago. The genera *Sahelanthropus*, *Orrorin*, and *Ardipithecus* are largely known from different parts of the skeleton, and all of them have been disputed as hominids in one way or another—reflecting the fact that as yet we have no clear idea of what the earliest hominid *ought* to look like. What they all have in common, however, is that each genus has been claimed on one slender basis or another to have been an upright biped. In the period between about 10 and 7 million years ago the ancient African forests began to fragment as the climate became less humid and more seasonal, and this clearly provided new ecological opportunities for terrestrial bipeds. Small wonder, then, that this adaptation has become the de facto criterion for membership in Hominidae. However, it still remains possible, even likely, that upright bipedality evolved more than once within the ancestral group from which both living apes and humans are descended.

The best-documented early bipedal hominid species is *Australopithecus afarensis*, known from sites in eastern Africa dating between about 3.8 and 3.0 million years ago. Exemplified by the famous “Lucy” skeleton, this species was small-bodied, standing between about 31½ and 41½ feet tall. Such creatures retained a variety of features useful in climbing, though they show a variety of pelvic and hind-limb specializations for bipedality, and would certainly have moved bipedally when on the ground. Above the neck, however, the proportions of *A. afarensis* were apelike, with a large face hafted onto a small, ape-sized braincase—which is why paleoanthropologists often characterize these early hominids as “bipedal chimpanzees.”

This combination of features was a remarkably successful one, remaining essentially stable as a whole variety of species of such “archaic” hominids came and went over the period preceding about 2 million years ago. Living on the fringes of the forests and in the newly expanding woodlands, hominids like *A. afarensis* probably subsisted primarily upon plant foods, although they may have scavenged the remains of dead animals and hunted small mammals much as some chimpanzees do today.

It was presumably a hominid of this archaic, small-brained kind that first began to manufacture stone tools

We sell more bones to artists than we do to science. • **Ronald Cauble,**
manager of The Bone Room (Berkeley, California)

around 2.5 million years ago. Consisting of small sharp flakes struck from one river cobble using another, these tools were crude but remarkably effective, and must have had a profound effect on the lives of their makers, allowing them, for instance, to detach parts of carcasses and carry them to safer places for consumption.

Early Hominids with Modern Body Proportions

Interestingly, no technological change marked the emergence at just under 2 million years ago of the first hominid species with body proportions essentially like our own. Built for life out on the broiling tropical savanna, far from the safety of the trees, it was most likely the unprecedented mobility of this striding biped, often known as *Homo ergaster*, that led to its almost immediate spread beyond the confines of Africa, best exemplified at the 1.8 million-year-old site of Dmanisi, in the Caucasus.

Technological innovation, in the form of the deliberately shaped “handaxe,” appeared later, also in Africa, at about 1.5 million years ago. During this period there also began a trend toward hominid brain-size increase, although the exact pattern of that increase will have to await better understanding of hominid diversity through this period.

By about 1 million years ago hominids had penetrated Europe and had begun to diversify there in a process that ultimately culminated in *Homo neanderthalensis*. This hominid had a brain as large as our own, albeit housed in a very differently structured skull. Meanwhile, the lineage leading to *Homo sapiens* was evolving in Africa, although this stage in human evolution is poorly—albeit tantalizingly—documented by fossils. Both molecular and fossil evidence suggests that anatomically modern *Homo sapiens* had emerged in Africa by a little under 200,000 years ago, and by around 100,000 years ago such hominids had reached Israel, which was also at least sporadically occupied by Neanderthals around this time. Interestingly, in the period of coexistence between about 100,000 and 50,000 years ago, the Neanderthals and moderns of the eastern Mediterranean region shared essentially the same technology. During this time,

though, we find the first stirrings in Africa of the symbolic behavior patterns that characterize *Homo sapiens* worldwide today.

Shortly after a more sophisticated Stone Age technology was developed in Israel, presumably by *Homo sapiens* whose ultimate origins lay in Africa, the local Neanderthals disappeared, and in short order Europe was invaded by modern peoples, at about 40,000 years ago. These “Cro-Magnons” left behind them an amazing record of virtually the entire panoply of modern symbolic behaviors, including representational and geometric art in various media, music, notation, bodily ornamentation, elaborate burial, and so forth. At the same time, technologies became enormously elaborated and embarked upon a pattern of constant innovation and change. Earlier hominids had adapted old tools to new purposes as environments changed; but cognitively modern *Homo sapiens* typically accommodated to such change by inventing new technologies.

The sequence of events just summarized strongly suggests that, with the emergence of *Homo sapiens* in Africa, an unanticipated ability for symbolic cognition was born. This new cognitive potential was evidently acquired in an emergent event, in which a chance coincidence of biological acquisitions resulted in something entirely new. Made possible by a long evolutionary history, but not an inevitable result of it, the expression of this unprecedented potential (the biological underpinnings of which were presumably acquired in the reorganization that led to modern anatomy) had to await behavioral discovery, much as ancestral birds had feathers for millions of years before discovering they could use them to fly. Most plausibly, the behavioral releasing agent concerned was the invention of language, an activity that is intimately tied up with symbolic thought.

Once the transition to symbolic thought had been made, *Homo sapiens* was positioned to eliminate its hominid competitors such as the Neanderthals and to embark on an aggressive demographic expansion. At this initial stage all human societies were economically based on hunting and gathering; rapidly, however, sedentary lifestyles relying on the domestication of plants and animals were independently adopted in various parts of the world. Sedentarism then led to further population expansion, urbanization,

economic specialization, and the development of complex societies. And it also led to a redefinition of the relationship of *Homo sapiens* to the rest of the world: to what the paleontologist Niles Eldredge (1995, 101) has characterized as a “declaration of independence” from our surrounding ecosystems.

Implications of Paleoanthropology

The study of paleoanthropology teaches us above all that the process leading to the arrival on Earth of *Homo sapiens* was not one of constant fine-tuning over the eons. Rather, our cognitively unique species appeared in a short-term event that was emergent in nature, rather than representing the culmination of any preexisting trend. This entirely unprecedented event witnessed the replacement of a history of highly sporadic hominid innovation, in the context of very low population sizes, by patterns of demographic expansion and restless local invention in both the social and technological realms—even as the inherent limitations of human experience, together with an apparent reluctance to learn from such experience, guaranteed that similar patterns would tend to recur over and again.

Further, the prehistory of sedentary societies almost everywhere shows that technological overintensification has repeatedly combined with climatic vagaries to ensure eventual economic collapse—for reasons that are often due as much to innate human proclivities as to the external proximate causes. Despite its extraordinary ratiocinative abilities, *Homo sapiens* is not an entirely rational creature, and its history worldwide reflects that fact. Evolutionary psychology and other reductionist approaches to the contrary, we *cannot* understand our own history as that of a creature that is biologically perfected for—or even broadly adapted to—any particular way of behaving.

Pan-Africanism

Pan-Africanism is a political and social movement that has historically encouraged both a political agenda of African unity and a broad cultural orientation of black identity in Africa and the African diaspora. Its ideology has roots in the early nineteenth century, while its specific political program emerged in 1900.

The roots of the Pan-African movement lie in the ideas and efforts of several key nineteenth-century intellectuals and activists from the United States and the Caribbean. These individuals were responding to the oppressive institutions of slavery, racist discrimination and segregation, and colonialism, as well as to the racial-cultural and psychological oppression and denigration that reinforced these institutions.

Origins and Themes

Much recent research has demonstrated the significance of African culture among North American blacks from the time of slavery to the present, while such information concerning Caribbean black culture has long been well known. Thus, it is appropriate to locate the roots of Pan-Africanism in the slave experience itself, as that experience fostered the development of “African nationalism”—an effort by slaves to resist oppression and to “bridge ethnic differences” that “proceeded from an impulse that was Pan-African” (Stuckey 1987, ix).

Black abolitionists such as David Walker (1785–1830), Henry Highland Garnet (1815–1882), Maria Stewart (1803–1879), and Frederick Douglass (1817–1895) used their interpretations of African culture and ancient history from the time of Egypt

and Ethiopia to argue against slavery. They were also all influenced by the redemptive promise of Christianity, particularly as expressed in biblical references to Africa such as Psalms 68:31 (AV): “Ethiopia shall soon stretch out her hands unto God,” in which “Ethiopia” was taken as a synonym for Africa and African Americans. This quotation was widely used into the twentieth century.

Martin Delany (1812–1885), Alexander Crummell (1819–1898), and Edward Blyden (1832–1912) were all primarily black nationalists, though with significant differences. All three actually experienced Africa: Delany traveled to the Niger valley and Liberia while Crummell was a missionary for twenty years in Liberia before returning to the United States, and Blyden emigrated from St. Thomas in the Caribbean to live in both Liberia and Sierra Leone. Delany is credited with originating the phrase in 1861, “Africa for Africans,” one of the later slogans of the Pan-African movement, though the original formulation was actually “Africa for the African race, and black men to rule them. By black men I mean, men of African descent who claim an identity with the race” (quoted in Brotz 1992, 110), which significantly implied a key role for African-American emigrants to help uplift Africa.

Alexander Crummell, like Delany, was a nationalist who also supported small-scale emigration to Africa. But he was primarily a missionary who had very little interest in or knowledge of indigenous African culture and called for the Christianization of Africa in order to “civilize” it. In contrast to Crummell, Delany was much more secular in his approach and advocated the emigration of free blacks to Africa with skills in teaching, medicine, business, transportation and other fields.

Portrait of Henry Highland Garnet (c. 1881). Albumen silver print. Garnet and other abolitionists drew on the redemptive promise in biblical references to argue against slavery. National Portrait Gallery, Smithsonian Institution.

Edward Blyden was the most significant black scholar of the nineteenth century, with complex and sometimes contradictory views of Africa. According to the historian Hollis Lynch, as early as the 1870s Blyden originated the concept of the “African personality,” by which he meant the unique characteristics of African culture and psychology, a notion that presaged the negritude movement of the twentieth century. Blyden had a great influence on West African nationalists and Pan-African theoreticians. In the words of Lynch, “Blyden’s pan-Negro ideology was undoubtedly the most important historical progenitor of Pan-Africanism” (Lynch 1967, 250).

Thus some of the early ideas leading to Pan-Africanism included black nationalism, the idea of Africa for Africans, emphasis by some but not all on a return to the African homeland, and the concept of the greatness of African history and culture, emphasizing Egypt and Ethiopia as black civilizations.

Other aspects emphasized by some included the need to uplift and regenerate Africa through missionary activity in order to fulfill God’s promise as expressed in Psalms 68:31.

Political Pan-Africanism

In his path-breaking and controversial paper, “The Conservation of Races,” delivered in 1897 at the American Negro Academy, W. E. B. Du Bois (1868–1963), who had recently earned his doctorate and Harvard, and who later became known as the father of Pan-Africanism, called upon African Americans to “take their just place in the van of Pan-Negroism” (quoted in Foner 1970, 79). Du Bois called for “race organization,” “race solidarity,” “race unity,” and a spirit of self-help, since “for the development of Negro genius, of Negro literature and art, of Negro spirit, only Negroes bound and welded together, Negroes inspired by one vast ideal, can work out in its fullness the great message we have for humanity” (Foner 1970, 79). Inspired to a large extent by Alexander Crummell as well as by European nationalist theorists, Du Bois in the late 1890s began his transformation first into a race man (a person primarily concerned with African American issues in the late 1890s) and eventually into a Pan-Africanist advocate and organizer.

The most important early political organizer of Pan-Africanism, however, was not Du Bois, but Henry Sylvester Williams (1869–1911), a lawyer from Trinidad resident in London since 1896. He founded a black organization called the African Association on 24 September 1897. The first documented use of the phrase “Pan African Conference” is found in an 1899 letter by Williams calling for a meeting in 1900.

The Pan-African Conference met 23–26 July 1900 in London. Approximately thirty-eight delegates attended from the United States, the Caribbean, and Africa. The delegates agreed to form a permanent Pan-African Association with headquarters in London and branches overseas, and to hold future meetings.

Du Bois was chosen chairman of the Committee on Address, which wrote the “Address to the Nations of the World” adopted at the end of the meeting. The Address contained one of Du Bois’s most famous statements, which later appeared in revised form in his 1903 book, *The Souls of Black Folk*: “The problem of the twentieth century is the problem of the color line” (Foner 1970, 125; Du Bois 1961, 23). The main points of the Address were appeals to end racism and economic exploitation and to “give, as soon as practicable, the rights of responsible government to the black colonies of Africa and the West Indies” (Foner 1970, 126).

This 1900 meeting was thus significant as the first Pan-African gathering, but Sylvester Williams’s tireless efforts did not result in a permanent organization. Williams began to focus on his law career instead of Pan-African organizing, and the people who had promised to follow up on organizing local chapters and the next international conference failed to do so. Consequently, The Pan-African Association was defunct by 1902, and Williams died in Trinidad in 1911.

The practice of convening international Pan-African meetings was revived by Du Bois, who in 1919 organized what he called the First Pan-African Congress (as opposed to conference), which met in Paris at the same time as the post-World War I Peace Conference. The fifty-seven delegates from Africa, the United States, and the West Indies adopted a resolution stating that “the natives of Africa must have the right to participate in the Government as fast as their development permits, in conformity with the principle that the Government exists for the natives, and not the natives for the Government” (quoted in Langley 1979, 740).

The 1921 Pan-African Congress was held in three sessions in London, Brussels, and Paris with 113 delegates. Du Bois delivered the presidential address, and the delegates endorsed a “Declaration to the World” that called for “local self-government for backward groups” (Padmore 1972, 109). A delegation headed by Du Bois presented a petition to the Mandates Commission of the League of Nations calling for the

Portrait of Edward Wilmot Blyden (c. late 1800s). As early as the 1870s Blyden originated the concept of the “African personality,” by which he meant the unique characteristics of African culture and psychology. Library of Congress.

appointment of “men of Negro descent” to the Commission, and for the formation of an “international institute for the study of the Negro problem” (Padmore 1972, 112). (The “Negro problem” referred to worldwide racial discrimination, including colonialism.)

Du Bois was the chief organizer for two more meetings, in 1923 and 1927. The 1923 meeting took place in London and Lisbon. At the London session the resolution adopted demanded that Africans be granted a voice in their government and access to land and resources and that Africa be developed “for the benefit of Africans, and not merely for the profit of Europeans” (Padmore 1972, 118). The 1927 congress, held in New York City, generated no significant new demands.

Du Bois wanted to hold the next congress on African soil and proposed Tunis in 1929, but the French

Portrait of W. E. B. Du Bois. Du Bois called upon African Americans to “take their just place in the van of Pan-Negroism.” Library of Congress.

colonial government refused permission. The worldwide economic depression and the rise of Fascism and Nazism prevented efforts to hold any more Pan-African meetings between 1927 and 1945.

The Garvey Movement

Marcus Garvey (1887–1940), a Jamaican immigrant to the United States, organized and inspired a whole set of Pan-African ideas and activities in the 1920s. His efforts are primarily significant due to his mass appeal, his efforts to stimulate emigration to Africa, and the example he set by forming local chapters of the Universal Negro Improvement Association (an organization he founded in Jamaica in 1914) around the world. In 1918 he founded a paper called *Negro World*, and he held annual conventions of the UNIA beginning in 1920 that aroused great emotional excitement. His movement influenced some future leaders of Africa and the

development of Rastafarianism in Jamaica and the Nation of Islam in the United States. But a steamship line that he started failed, and he was convicted of mail fraud in 1923, served three years in prison, and was deported back to Jamaica. He died in London in 1940.

Ethiopia and Pan-Africanism

The Italian Fascist invasion and occupation of Ethiopia between 1935 and 1941 brought unprecedented worldwide attention to the Pan-African symbol of Ethiopia. The biblical Ethiopia, as in Psalms 68:31, continued to be a symbol for the rising hopes for black freedom, but by the late 1890s African-Americans began to gain more specific knowledge about Ethiopia, the country. One stimulus for this increased interest was the Battle of Adwa on 1 March 1896, in which the armies of the Ethiopian emperor Menilek II (1844–1913) overwhelmingly defeated the invading forces of Italy. As the only military resistance that successfully preserved the independence of an African country in the era of European colonialism, this battle was widely reported in the black press and sparked a tremendous worldwide interest in the country. After Adwa, diplomatic and personal contacts increased between Ethiopians and African-Americans, particularly after the young heir to the Ethiopian throne, Ras (Prince) Tafari Makonnen (1892–1975; known after his 1930 accession as Haile Selassie) sent the first official Ethiopian mission to the United States in 1919.

These increased connections may be illustrated by the career of Malaku Bayyan (or Bayen, 1900–1940). Malaku (Ethiopians go by their first name) attended college in Ohio in the 1920s. In 1929 he entered Howard University Medical School, from which he graduated in 1935. He later stated, “My belief in Race Solidarity caused me to select Howard University for my studies, in order that I might have a closer contact with my people” (quoted in Harris 1994, 22). He married an African-American who was working at Howard, and he traveled back

and forth between Ethiopia and the United States in the 1930s.

After the defeat of Haile Selassie's armies in 1936, the emperor went into exile in England and ordered Malaku "to coordinate the black solidarity movement" in the United States and specifically to take control of the collection of funds for the scattered Ethiopian refugees (Zewde 2002, 206). In 1937 Malaku founded the Ethiopian World Federation and a newspaper, *Voice of Ethiopia*, whose slogan was "Ethiopia is Stretching Forth Her Hands unto God" (Harris 1994, 130). The paper saw itself as the successor to Garvey's *Negro World*, but advocated the use of "black" instead of "Negro" as a term allowing a greater sense of unity among African Americans, West Indians, Ethiopians, and other Africans. It had a clear Pan-African perspective, stating, "We are out to create a United States of Africa" (Harris 1994, 131).

Pan-Africanism Since World War II

Two important supporters of Ethiopia in Britain in the 1930s—George Padmore (1900–1959) and T. Ras Makonnen (1899/1903–197?), a name adopted by George Thomas Nathaniel Griffith in honor of RasTafari Makonnen)—illustrate the Pan-African connections of the Ethiopian and World War II movements. Padmore was born Malcolm Nurse in Trinidad and adopted his new name when he joined the Communist International in the late 1920s, but later rejected the "pretentious claims of doctrinaire Communism" (Padmore 1972, xvi) in favor of African nationalism and Pan-Africanism." Makonnen was from Guyana but claimed Ethiopian ancestry. He lived in the United States, England, Ghana, and Kenya, and acted through a plethora of personal contacts with people of African descent in the diaspora, using face-to-face lobbying and advocacy in cases of police brutality or colonial injustices, thus exemplifying "practical Pan-Africanism."

Makonnen's business acumen enabled him to help finance and organize the Pan-African Federation, formed in 1944 by the merger of several groups, including the International African Service Bureau

that had been formed in 1937 to support Ethiopia. The Pan-African Federation organized the 1945 Manchester Pan-African Congress and continued into the postwar era, as did Makonnen's journal, *Pan-Africa*.

The 1945 Pan-African Congress marked a significant revival of the movement, being the "largest and most representative Pan-African Congress yet convened" (Padmore 1972, 127). Delegates to this congress included some of the leading future political and intellectual leaders of Africa and the Caribbean. At the age of seventy-seven, Du Bois also took an active part in the proceedings.

The resolutions of this congress were more radical than any previous ones. They rejected all euphemisms for colonial rule, such as partnership, trusteeship, guardianship, and the mandate system, demanding "autonomy and independence," and the right of all colonies to be "free from imperialist control, whether political or economic" (Langley 1979, 758, 760).

Political Pan-Africanism after 1945 has consisted of the ultimately contradictory movements for national independence and African unity. Culturally, Pan-Africanism has involved a series of conferences of black writers and artists, held periodically since 1956, and the publication of the journal, *Presence Africaine*. The political movement was led by Kwame Nkrumah (1909–1972), the head of state of independent Ghana from 1957 to 1966. He sponsored two Pan-African meetings in 1958, the Conference of Independent African States, and the more significant All-African Peoples' Conference, the latter described as the "true successor" to the series of Pan-African congresses (Wallerstein 1967, 33).

Julius Nyerere (1922–1999), the leader of Tanzania from 1961 to 1985, supported the cause of liberation in southern Africa, playing a significant role in the Liberation Committee of the Organization of African Unity (OAU), formed in 1963, and hosting liberation movements. He also hosted a Pan-African Congress at the University of Dar es Salaam in 1974. This congress was spearheaded by African-American and Caribbean activists who developed a consensus theme of "self-reliance, self-determination

African nationalism is meaningless, dangerous, anachronistic, if it is not, at the same time, Pan-Africanism. • **Julius K. Nyerere (1922–1999)**

and unity of black people throughout the world” (Abdul-Raheem 1996, 7), emphasizing participation by people’s organizations and liberation movements rather than governments. Yet another Pan-African Congress was held in Kampala, Uganda, in April 1994. By that time, the political independence of the continent was essentially complete, and the congress dealt with such important issues as reparations, economic development, democracy, social problems, science and technology, and the women’s movement.

These issues and others reflecting the realities of Africa today show the continuing need for Pan-African based actions. Though there is as yet no United States of Africa, there is a growing recognition among African leaders and thinkers that Africa must unite in some form. At present, there are at least twelve economically based regional groups, such as the Economic Community of West African States, the Common Market for East and Southern Africa, the Economic Community of Central African States, and the Southern African Development Community. Moreover, the OAU has been transforming itself into the African Union during the last several years, and has stated an aim of creating an African Economic Union in the next two decades. Achieving the increased unity needed to deal with internal African problems may be the most significant hurdle of the current Pan-African agenda. Although Africa and the African diaspora have made great progress in the last two centuries, work remains for Pan-Africanists and their supporters in the present and the future.

Paper

The secret of manufacturing paper, which originated in China, spread with printing; before long, printing on paper enormously increased the flood of information sustaining the world. Rags and vegetable fibers were first used to make paper; since the nineteenth century, whole conifer forests have been felled to supply enough wood pulp to meet papermaking demands.

Paper, a thin, felt-like material made of cellulosic fibers from plants, is widely used around the world for writing, drawing, and wrapping. The English word *paper* derives from the similar material used by ancient Egyptians, Greeks, and Romans: papyrus.

Antiquity

Predecessors of paper, known by the generic term “tapa,” are found in nearly all cultures in the equatorial zone and are used also for decorating and clothing. They are produced by beating the inner bark of plants such as the paper mulberry, fig, or daphne. In ancient Egypt, papyrus was made accordingly from the pith of the papyrus plant.

The oldest papermaking technique—still in use in a few locations in the Himalayas, China, and Southeast Asia—derives from a combination of this pounding technique and felting techniques (felting involves pressing together materials so that they adhere to form a large whole). To make a pulp, plant bark that has been cooked is beaten with a wooden hammer to form a thin fibrous layer that then is dissolved in a vat with water. The papermaker pours the quantity of pulp needed to make one sheet onto

a mold consisting of a wooden frame with a fabric or bamboo screen and spreads it with his hand evenly across the screen. The mold is lifted carefully; the water drains off and a sheet of paper forms on the screen. Then the mold is placed in the sun or near a fire to dry. When dry, the sheet easily peels off the screen and, apart from possible smoothing, requires no further treatment.

As recent findings of very old paper in Chinese tombs show, paper has been produced in China ever since the last two centuries BCE. In 105 CE, the court official Cai Lun allegedly invented papermaking from textile waste (that is, rags). This was the birth of paper as we know it today. Chinese papermakers developed a number of specialties, including sizing (making the paper ink-proof), coating, and dyeing. They introduced bamboo as a fiber plant, beating it after cooking it in lye. Paper served for such diverse purposes as writing, drawing, wrapping, clothing, protection from weather, decoration, windows, and even for balloons and kites. Last but not least, paper was used for special currency to be burned in honor of the ancestors.

The Spread of Papermaking

Chinese papermaking techniques reached Korea at an early date and in 610 were introduced to Japan, where papermaking was becoming a skilled craft. The ultimate was the production of *shifu*, paper yarn woven into beautiful fabric.

Knowledge of papermaking also spread from China to Central Asia and Tibet, and then on to India. The Arabs, in the course of their eastern expansion, became acquainted with the production

Making paper by hand requires dipping a mold into a vat of pulp and lifting out just enough to make a sheet of the desired thickness.

of the new writing material near Samarqand, and paper mills were subsequently set up in Baghdad, Damascus, Cairo, and later in Morocco and Spain. Using screens made from reed, the Arabs made thin sheets of rag pulp and coated them on both sides with starch paste, which could be colored. This gave Arab paper its good writing properties and its fine appearance. Arab technique spread into medieval Europe, and European innovations, especially the paper machine (multiplying the production rate), spread throughout the world during the nineteenth century.

European Handmade Paper

In medieval Italy, papermakers from Genoa, Fabriano, and Amalfi tried to improve on the Arab technique. Their innovations included the use of water power, stamping mills (derived from fulling mills, which shrank and thickened cloth) to pound the rags, molds made of wire, couching (setting the forming paper on a felt to be pressed), the screw paper press, dip sizing with animal glue, and a production process based on division of labor.

Three kinds of paper were produced: writing paper, printing paper (mostly unsized), and cheap wrapping paper, also used for drafts. Printing paper caused the evolution of the graphic arts (woodcut; engravings). Work at the vat normally involved four people: the vatman, who made the sheet using the mold; the couchman, who worked in time with the

vatman, placing the sheet on the felt; the layman, who removed the moist sheets from the felt after pressing; and the apprentice, who had to feed pulp to the vat and keep the vat heated. Up to nine reams (4,500 sheets) of paper could be made during a working day averaging 13 to 15 hours.

Technical progress continued. In the sixteenth century, hand glazing (polishing) using a glass or stone burnisher was supplemented by the use of the glazing hammer similar to a forging hammer. Toward the end of the seventeenth century a much more efficient tool, the so-called hollander beater, supplemented or even replaced the stamping mill.

Watermarks

The watermark, invented in medieval Italy, provides the historian with an unsurpassed dating and authenticating tool. The real watermark, a figure in the paper sheet, is seen by the naked eye. In hand papermaking, it is formed by a curved wire that is sewn onto the screen of the mold; the wire reduces the thickness of the sheet, thus making the figure transparent. Later, after the invention of the paper machine, a roll covered with wire gauze impressed the watermark on the wet paper web. The watermark serves as a papermaker's trademark. By comparing a watermark with others of a certain date or origin, the paper historian is able to determine age and origin of a document or print. Shadow (countersunk, embossment, intaglio) watermarks are produced on a mold that carries a fine, embossed woven wire, and appear as images, like a black-and-white photograph.

The Advent of Industrial Papermaking

From the sixteenth century, paper became more and more important for administrative and commercial purposes, and, as more people were trained in writing and reading, for private use, too. The debates of the church reformers and new works of science were widely published by printing on paper, and popular pamphlets, romances, and plays were distributed in print all over Europe. Newspapers, which from the

beginning of the seventeenth century had come out with weekly issues, changed during the eighteenth to a daily format, and became—censored by the government in most countries—the sole means of shaping public opinion and spreading news of scientific progress. The ideas of the Enlightenment and of the French Revolution were supported by the development of the print mass media at the end of the eighteenth century.

Further developments in printing during the eighteenth and nineteenth centuries resulted in a steeply rising demand for paper, especially for new printing grades. This and the tremendous upsurge in papermaking soon led to a serious shortage of raw material and to regulations governing the trade in rags to ensure the local production of paper for administrative purposes. The systematic search for substitute pulping materials met with little immediate success.

Already in the eighteenth century, there had been some concentration of handicraft activities in big factories, which still depended on skilled papermakers organized in open guilds. Efforts to step up production and to have many jobs done mechanically culminated in the design and construction of paper machines. A Frenchman, Nicholas-Louis Robert (1761–1828), built the first paper machine using an endless wire screen, patented in 1799. It was further refined in England by Bryan Donkin (1768–1855) and by Henry (1766–1854) and Sealy Fourdrinier (d. 1847). Soon, other types were developed, such as the Dickinson cylinder machine. Fourdrinier-type and cylinder machines gained ground in the nineteenth century and were extended to include a dryer section; the technology steadily improved, leading to considerable increases in production speeds. With the increasing industrialization of papermaking, small operators who were unable or unwilling to pay for machines were forced to survive with piece work or by producing special grades and cardboard, but they were sooner or later compelled to discontinue their activities.

A Chinese papermaker at work.

The decisive turn in developing the U.S. paper industry was initiated by Joshua Gilpin, who in 1815 brought from England not only the plans of the Dickinson cylinder machine but also Lawrence Greatrake, a leading paper engineer. Special paper machines were successfully built (including the so-called Yankee cylinder machine), and soon the United States led the world in paper production and in per capita paper and board consumption (more than 300 kilograms per year in 1980).

The industrialization of papermaking was marked by some definite trends. First, all work sequences previously performed by hand were mechanized, thus steeply raising the demand for energy. Then, efforts were made to obtain rag substitutes on an industrial scale, and appropriate industrial plants were developed. Straw was suggested as a raw material but proved unsuitable because it produced low-quality paper. Only the 1843 discovery that one could use ground wood pulp, followed by the invention of chemical pulp (first patents in 1854), solved this problem. Pulping (the extraction of fibers from wood by mechanical or chemical means) became an industry of its own. Just from its start, two big problems arose: wood grinding produced fibers of minor quality, prone to decay in a short term, especially if applied together with acid rosin size. Thus, most books and newspaper produced between 1850 and 1980 containing

*I put a piece of paper under my pillow, and when I could not sleep
I wrote in the dark.* • **Henry David Thoreau (1817–1862)**

wood pulp are endangered and need conservatory treatment. Because of heavy water and air pollution, chemical pulping plants were—already in the nineteenth century, together with the then newly founded chemical plants producing synthetic dyestuffs—the first targets of popular ecological movements and legislation. A further stage was marked by the enlargement of the web width (*web* is the term for the continuous sheet of paper produced in mechanized paper mills), an increase in working speeds, the introduction of electric drive, and the development of machines designed specifically for the production of particular paper and cardboard grades. Web working width grew from 85 centimeters in 1830 to 1,100 centimeters in 1990, while production speeds rose from 3 to 5 meters per minute in 1820 to more than 2,000 meters per minute in 1995. Consequently, paper prices dropped, leading—starting also in the nineteenth century—to the production of very cheap booklets and magazines intended for a growing literacy of peoples around the world.

Alongside the development of printing, new paper grades were created, together with specialized paper such as punch cards, stand-up collars, tube papers, flong (stereotyping paper), pergamyn (parchment imitation), ammunition papers, envelopes, tobacco paper, toilet paper, and so on. The use of new materials (thermomechanical pulp, deinked waste paper, new fillers, process chemicals, and dyes) and new sheet-forming techniques, neutral sizing, greater stress on ecology, and—most effective—automation brought further improvement.

Paper Today

Paper consumption grew from medieval times to the end of the eighteenth century by a factor of fifty. Since then, paper and board has become a worldwide, large-scale commodity with exponential growth. Statistics from the United Nations' Food and Agriculture Organization (FAO) have led to a forecast of about half a billion tons in 2010, of which about two-fifths

will be produced in the fastest growing industrial market, Asia.

Technical and commercial changes have led to specialization in certain paper types, development of new paper grades, and new commercial entities and structures brought about by corporate mergers or by company groups with their own raw-material supply and trading organizations. The evolution of new sheet-forming principles and chemical pulp processes, along with increased demand in the global market (especially in developing countries), trends in chemical pulp prices, and location problems are again increasing the capital needed to be a successful competitor, which in turn is leading to the formation of big company groups with international operations. Papers for technical use form an increasing market.

Environmental problems have led to changes, too. Introduction of new forestry principles, fiber recycling from waste paper, heat recovery, closed water circuits, and replacement of aggressive chemical processes in pulping have improved the formerly poor image of the pulp and paper industry. Up to 60 percent of the total fiber consumption is covered by waste paper, thus saving forests from over-cutting. Modern papermaking processes are running quicker, consuming less water and energy, minimizing pollution, and are again producing long-lasting paper.

The electronic revolution in data processing and private and public communication appears not to be affecting reliance on paper and probably will not until an easier-to-handle, more lasting, cheaper storage medium for the memory of mankind is found. Even then paper will remain a ubiquitous helper (for example, in packaging and hygiene) in daily life.

Parliamentarianism

Parliamentarianism, as it originated in eighteenth- and nineteenth-century Britain, gave power to elected representatives in the legislative branch of the government, securing property rights for the landed gentry and diminishing power of the absolute monarchy. It aimed to stabilize government administration and provide orderly transfer of power, both at home and in British colonies. The Industrial Revolution and the growing power of trade unions contributed to its decline, although a modified form of the system exists in Canada, Israel, Scandinavia, and the European Union.

As an organizing principle of a governance structure, *parliamentarianism* comes from modern Britain and is an early variant of constitutional monarchy. It designates a functional, relatively free, civic framework that seeks harmony and prosperity through preventing or managing political conflicts while endowing real power in the legislative branch, which, in turn, represents the will of the people (or, initially, the males who owned considerable property).

Parliamentarianism assured a high degree of stability while diminishing the ruling capacity of absolute monarchy. In its positive and preferred form, the expectation is that an accountable and incumbent sovereign government will enjoy the expressed will of a working majority of elected representatives. A lesser, negative option demands that, if a minority government exists, it will be supported, or at least tolerated, by the legislature, as demonstrated by the government's not being defeated in routine votes. Parliamentarianism guarantees that authority and power is possessed and is operational at all times,

avoiding long periods of caretaker, unstable, or interim regimes.

The framework is akin to that of constitutional monarchy, but with rule-based parliamentary tradition and unwritten political conventions as the pivot of democratic life, rather than chartered documents or explicit regal prerogatives. The legal foundation of this structure is a substitute for a written constitution, which most kings and queens opposed as it would explicitly constrain the powers vested in their office and their public influence. Concomitantly, parliamentarianism assured the elite, political class of substantial impact on the routine formation and implementation of economic, social, diplomatic, and defense policies.

In the British system the governing party, as long as it has an effective mandate between elections, wields executive powers, composing and leading the cabinet. The term of office could last up to five years, but it typically was around four years. Within the maximum of five years that a parliament could be incumbent, it was at the discretion of the prime minister to ask the monarch to dissolve the House of Commons. Indeed, the full authority and the wide discretion exercised by the incumbent prime minister were at the heart of this system. Having the distinction of being the leader of the largest party and the most prominent member of Parliament from the House of Commons, the prime minister increasingly served as a viable substitute for the reigning monarch. Parliamentarianism thus accommodated the rise of the professional, urban, unhereditary, non-land owning, upper class by transferring political power to them from the monarchy and aristocracy.

The loss of an important vote—the approval of an annual budget or the ratification of vital domestic measures or crucial agreements with other

countries—causes the instantaneous resignation of the prime minister and his cabinet and/or the immediate calling of new elections. This pattern though not written down, served as a binding convention in the British political culture. Securing a new mandate from the voters was essential even if only a short time has elapsed since ballots were previously cast. New elections were scheduled immediately. Campaigns lasted a few short weeks. The transfer of power from the defeated party to the winning one, if the election results dictated that, was a speedy process amounting to only days after results were officially proclaimed, which, in turn, was also obtained within days.

History

The Glorious Revolution of the seventeenth century capped a political process that began with the Magna Carta of 1215, the result of widespread resentment of the absolute, authoritarian aspirations of the monarchy. Aristocrats and members of the upper middle class had increasing authority in England, then in the rest of Britain, and, eventually, in its colonies overseas, deciding most issues of public policy. The balance of power gradually shifted to the landed gentry and to an emerging group of liberal urban professionals (the Whig party) who supported the ideas of classic liberalism and were active in society, economic life, intellectual discourse, and diplomacy. Political supremacy, sometimes cloaked in civic and economic rights, was thus increasingly based on a mandate that the legislative chamber increasingly defined the duties and the privileges of kings and queens.

The pattern of vesting real power in members of the British Parliament aimed to revitalize representative government while securing property rights. It developed in the eighteenth and nineteenth centuries. Coupled with the first post-the-ballot electoral structure—which granted seats for the candidate with the highest number of votes in each district, rather than apportion them to parties by the percentage of votes received overall—the typical result

was a two-party system. Inside the bicameral legislature the House of Commons gradually replaced the House of Lords as the senior partner within the structure of enacting and implementing legislation. This change positioned parliamentarianism at the center of government life and bureaucratic transparency (bureaucrats and their acts were subject to Parliament's consistent review and assessment) in the United Kingdom.

The absolute control of the British government was alternately held by the Liberals (Whigs) or the Conservatives (Tories), rather than by a third party or a wide coalition, even during prolonged wars. Dominant prime ministers included the Conservative Benjamin Disraeli (1804–1881) and the Liberal William E. Gladstone (1809–1898), who alternated in power during the second half of the nineteenth century.

Impact

While practically guaranteeing an unbreakable sequence of stable administrations and an orderly transfer of political power, there were severe consequences to this scheme. Civil service positions, especially those of permanent undersecretaries, became very influential as it was the people who held these positions continuously who ran governmental departments. These position holders came from the ranks of prominent families and elite schools. They largely represented the interests of the upper classes, which were naturally disposed to inhibiting reforms or repudiating radical alternatives. Prime ministers could, and sometimes did (especially around the middle of their terms), shuffle portfolios among different officials, even within the same cabinet, decreasing the tenure of ministers in the same position. As a result, long-term bureaucrats often decided policy issues, not merely implemented them. Furthermore, this conservative hierarchy was considerably less sensitive to sectarian interests, the advancement of economic reforms and social mobility, and the well-being of colonial communities, or else subordinated these concerns to the concerns of major factions and large corporations based in the British Isles.

American Dissent

Settlers in North American colonies during the 1760s and 1770s increasingly resented this rigid framework. It deprived them of adequate access to decision-making that concerned their daily lives. This pattern was epitomized in the slogan “no taxation without representation” adopted by Benjamin Franklin (1706–1790), who was well acquainted with the British, having lived in London. He led the movement that also vigorously opposed the “virtual representation” system, which allowed well-connected politicians access to legislative power although they did not have any constituencies (representing “corrupt boroughs”), then prevalent in Britain. Furthermore, the subsequent U.S. system of a balance of powers (“checks and balances”) among the three branches of government—executive, legislative, and judiciary—and the relative independence of the presidency from Congress, as drawn up in a written constitution, were, in part, responses to the perceived excesses and shortcomings of parliamentarianism.

Irish Exclusion

Ostensibly, Irish Catholics, British subjects until the 1920s, had power equal to that of other voters. In reality, however, they were misrepresented by the politics of the British system, including the property requirements that limited suffrage. Their distinct ethnic and religious interests, moreover, were either left to sectarian parties that did not have realistic chances of reaching power nationally or were subsumed by parties whose main constituents were English and Irish Protestants. This lack of representation was one of the major reasons for the demand for Irish home rule in the nineteenth century, subsequently leading to independence after World War I.

Decline of Parliamentarianism

The impact of the Industrial Revolution in Britain changed the internal political structure, beginning in the mid-nineteenth century. In the early 1900s the

Oliver Cromwell, a key figure in the English civil wars, was a member in 1640 of Charles I's Short (three-week) Parliament and Long Parliament (so named because it could only be dissolved by the agreement of its members).

Victorian age passed with Queen Victoria, who was succeeded by mediocre, much less impressive monarchs. The concomitant rise of trade unions and the Labour Party representing the wider franchise of the working classes and non-English elements (such as the Scots) within Britain broke the hold of the traditional, wealthy establishment. Culminating a process that had lasted decades—and with the turmoil of World War I (1914–1918) and the rise to power of the Labour Party—power shifted away from the restricted halls of Parliament into the more public arena.

Nevertheless, a modified form of the British parliamentary system continued in existence, especially in the developing world, in countries that used to be controlled by the British (the “Westminster System”). Westminster is the British system of a democratic, deliberative, representative parliamentary in control of state affairs through a government formed by the party that has a majority in Parliament and an independent judiciary. In a pattern similar to that leading

to the creation of U.S. institutions, this democratic legacy of colonialism is in competition with the American hybrid of checks and balances between a Congress and a president, both of whom are directly elected by the people, rather than a prime minister selected by a Parliament.

Scandinavia

Although Scandinavia was never a part of the British Empire, there was enough awareness of and affinity with Great Britain—through commercial connections and geographical proximity—that the result was that unique versions of parliamentarianism as an organizing principle within constitutional monarchies developed.

Sweden

In Sweden the framework was put into place in 1907, with a parliament, the *Riksdag*, as the focal point of political power. This emulation of the British system was a major part of wide reforms that introduced universal franchise and aimed to neutralize class antagonism and tensions between growing urban and rural populations. Unlike those in Britain, however, many governments in Sweden have been coalitions of at least two parties, making them inherently less stable.

Norway

Norwegian independence from Sweden was peacefully secured in 1905. Through the subsequent written constitution, a form of parliamentarianism was adopted; it was strengthened after occupied Norway regained its sovereignty in 1945, following Germany's defeat in World War II. The monarch, although occupying a hereditary position, has to pledge an oath to uphold the constitution and the laws of Norway, which provide for a universal franchise. After an election, the monarch appoints the leader of the largest party in Norway's parliament, the *Storting*, as the prime minister,

who then forms a government—if need be, a coalition that enjoys a working majority. Members of the cabinet are formally selected by the monarch but are nominated by the prime minister. Elections are customarily held every four years; the *Storting* can be dissolved earlier, but not during in its fourth year.

Israel

The State of Israel was created by the United Nations in 1948 out of the British Mandate of Palestine. Close to three decades of British control left its mark. A government cannot be established or survive unless it receives and maintains a working majority in the *Knesset*, Israel's parliament. In a role analogous to that of the British monarch, Israel has a president serving as titular head of state, one of whose major responsibilities is to designate a prime minister. A loss in a no-confidence vote does cause the fall of the government, but it does not trigger new elections without a specific law dissolving the current *Knesset*. Until a new cabinet is sworn in upon receiving confidence from the *Knesset*, the outgoing prime minister has full authority.

Caretaker regimes can remain in office for a relatively long duration. In March 1990, when the national unity alliance between Labor and the right-wing Likud collapsed over disagreements concerning the Arab–Israeli peace process, Prime Minister Yitzhak Shamir (b. 1915) took three months to form an alternative coalition. Between 1996 and 2001, a mixed system existed, under which two ballots were cast: one for a prime minister, the other for a party. The elected leader could start ruling only after forging a coalition that commands a majority in the *Knesset*.

In July 2000, following his controversial offers for peace with the Palestinians, Labor's Ehud Barak (b. 1942), who was elected in the previous year with a convincing individual majority (56 percent as compared with Likud's Binyamin Netanyahu's 44 percent) but with a weak party following (the one Israel bloc he led garnered merely 26 of 120 seats)

lost most of his coalition partners, thus the plurality in the Knesset. Nevertheless, because there was no absolute majority to topple him, Barak was only forced to call personal elections in December 2000 for February 2001. He remained as a prime minister one more month, even after his resounding defeat (38 percent to 62 percent) to Likud's Ariel Sharon (b. 1928).

Canada

Canada is a former British colony. It slowly became independent from 1867 to 1948. It is a leading member of the British Commonwealth, has adopted parliamentarianism, and the British monarch is the titular head of state. Canadian federalism allows a strong degree of autonomy to provinces. The federal parliament represents, almost proportionately (some preference to the Atlantic region that has a smaller population), the Canadian people. There is also an unelected Senate, to which the Prime Minister appoints by patronage, obviously a duplication of the British House of Lords. There were plans (like the 1992 Charlottetown Accord) to reform the system, but to no avail.

A particularly intriguing example of the workings of parliamentarianism can be found in the short tenure of Progressive Conservative Prime Minister Joe Clark (b. 1940). Clark led a minority government, after defeating in 1979 the former Liberal prime minister, Pierre Elliot Trudeau (1919–2000), who had served as PM for eleven years. Clark was supported by several independent right-wing members of Parliament from western Canada. In February 1980, after only eight months in office, Clark failed to secure sufficient support for his first annual budget. He was compelled to ask Canada's governor-general (the vice regal representative appointed by the British monarch) to dissolve the federal parliament. Clark lost in the ballots cast the following month, and Trudeau became, again, the prime minister, after only nine short months in the opposition.

Contemporary Europe

The European Union (EU) had grown from a French vision in 1950, and a humble start in which Britain did not partake, in the 1957 Treaties of Rome. The EU has become a continental powerhouse with complex institutions and a hybrid of structures. The EU is gathering more political momentum, adding new members, incorporating territory in southern and Eastern Europe, consolidating its laws, and proclaiming constitutional powers. The EU is increasingly independent from the countries that make up its rapidly expanding ranks. Parliamentarianism may become its guiding principle on the road to securing popular support for strong federalism. The formation of the European Parliament, as a body whose members since 1979 are directly elected and often represent ideological agendas and continental (rather than national) interests, also balances the influence of local politicians and state governments. While competition for authority will continue, real power seems to increasingly to be vested in an institution whose structure and procedures may resemble the traditional role of the British House of Commons, although the vast majority of EU members do not have a tradition of parliamentarianism.

Pastoral Nomadic Societies

Pastoral nomadic societies view the husbandry of grazing animals as an ideal way of making a living and consider the regular movement of all or part of their societies to be a normal part of life. Although this lifestyle produces a low population density, and the total number of nomads has always been relatively small, the impact of nomads on world history has been profound.

During two thousand years (500 BCE–1500 CE) the horse-riding nomads of the Eurasian steppes (usually level and treeless tracts of land in southeastern Europe or Asia), such as the Scythians, Xiongnu, Huns, Turks, and Mongols, created powerful states that presented significant challenges to their sedentary neighbors in China, Central Asia, Iran, Turkey, and Europe. The camel-raising desert Bedouins became key political actors in the Middle East and northern Africa after the rise of Islam during the mid-seventh century. In sub-Saharan Africa cattle-raising nomads such as the Masai and Zulus came to dominate much of the continent's grasslands by the end of the nineteenth century. These pastoral nomadic societies considered the husbandry of grazing animals a viable way to earn a living, and the habitual movement and relocation of their communities as a normal part of their lives.

Origins

Early theorists saw pastoral nomadism as evolving out of hunting and into sedentary agriculture. Archaeological evidence has largely upended this view because the first domestication of both plants (wheat and barley) and grazing animals (sheep and goats)

apparently took place in parallel more than nine thousand years ago in the Near East. Thus, rather than being a precursor of sedentary life, pastoral nomadism more likely developed as an economic specialization out of a mixed Neolithic (8000–5500 BCE) economy based on sedentary villages after 5000 BCE. The viability of such a nomadic specialization increased with the later domestication of cattle and more particularly with the domestication of baggage animals such as donkeys, horses, and camels. Only with the domestication of baggage animals or new technologies such as cattle-drawn carts and wagons beginning in the Bronze Age (c. 4000–3000 BCE to the Iron Age) were nomads able to effectively utilize truly mobile dwellings such as black goat-haired tents (yurts).

Recent ethnographic (relating to the study of cultures) work has largely discredited the notion of the “pure nomad” who subsists entirely on pastoral products, free of entanglements with the sedentary world. Historically pastoral nomads have always been tied economically and politically to their sedentary neighbors. Without such ties they could not easily survive.

Why Pastoralism?

Pastoral nomadism is commonly found where climatic conditions produce seasonal pastures that cannot support sustained agriculture. Because people cannot eat grass, exploiting grazing animals that can eat grass effectively taps an otherwise unusable energy source. Although historians generally use the terms *nomads* and *pastoralists* interchangeably, the terms are analytically distinct. The former term refers to movement and the latter to a type of subsistence.

Well-fed sheep on Golodnaia Steppe. Photo taken between 1905 and 1915 by Sergei Mikhailovich Prokudin-Gorskii. Library of Congress.

Not all pastoralists are nomadic, nor are all nomads pastoralists (hunter-gatherers or itinerant groups such as Gypsies).

Using portable tents or huts to facilitate migration, pastoral nomads rotate their animals through extensive but seasonal pastures. Migration cycles vary in time and length depending on local conditions. Nomads make relatively few moves when pastures and water supplies are dependable, many more moves when they are not. Although the degree of predictability in migration routes varies from group to group, pastoral nomads do not “wander”; they know where they are going and why.

Organization and Distribution

Pastoral nomadic societies are organized around mobile households rather than individuals, and everyone (men, women, and children) has a role in the various aspects of production. These characteristics distinguish pastoral nomads from European shepherds or U.S. cowboys who are recruited from the larger sedentary society to which they regularly return. All pastoral nomadic societies share such structural similarities as tribal organization and a strong bias

toward patrilineal (through the paternal line) descent and residence.

Pastoral nomadic societies are confined to the Old World. The only area of indigenous large-animal domestication in the New World was the high-mountain Andes in South America, where llama-raising communities were integrated parts of alpine farming villages and did not form separate pastoral nomadic societies. Sheep, goats, horses, donkeys, and cattle were introduced into the Americas only after the Spanish conquest during the 1500s. Although cattle raising became important in the western United States, Brazil, and Argentina, it was ranching done by sedentary people. The capture of horses from the Spanish during the mid-seventeenth century by natives of the U.S. Southwest did produce a classic nomadic society, the Plains Indians, but they were mounted hunters who followed herds of bison, an animal they never domesticated.

Main Types and Key Animals

The variety of animals raised by pastoral nomadic societies is surprisingly small: six widely distributed species (sheep, goats, cattle, horses, donkeys, and

camels) and two species with restricted distribution in Asia (yaks at high altitudes and reindeer at northern sub-Arctic latitudes). Dogs are also often kept for protection. Pastoral nomadic societies fall into six distinct types, each with a key animal that has primary cultural importance and a specific geographical range.

Eurasian Steppe: Horses

In the Eurasian steppe zone nomads give pride of place to the horse, although they also raise sheep, goats, cattle, and Bactrian (two-humped) camels. Although the domestication of the horse may have occurred as early as 4000 BCE, the emergence of horse riding after 1000 BCE laid the foundation of steppe nomadic power. Beginning in the seventh century BCE the Scythians and Sarmatians established distinct societies in south Russia and Ukraine. Their way of life spread east relatively rapidly until, by the third century BCE, culturally similar groups, Xiongnu, Wusun, Yuehshi, became well established on China's northern steppe frontier. For the next two thousand years a series of nomadic empires based there was to be China's greatest foreign policy challenge. The empires also controlled key links of the Silk Road, the overland trade route that linked China with the West.

The most powerful of these nomadic groups who successively bordered China were the Xiongnu, Turks, Uygurs, Mongols, Oirats, and Zunghars. In the West the best-known steppe nomads of the medieval and early modern periods included the Huns, Khazars, Kipchaks (Cumans), Golden Horde (Tatars), and Kalmuks. After the Mongol conquest the Kazakhs, Turkmen, and Kirghiz came to dominate Central Asia.

Southwestern and Central Asia: Sheep and Goats

The mountain and plateau areas of southwestern and Central Asia are dominated by pastoral nomadic societies who raise sheep and goats and use horses, camels, and donkeys for transport. Pastoral nomadic societies there have always had a symbiotic relationship with neighboring towns as economic specialists, trading meat animals, wool, milk products, and hides for grain and manufactured goods. Indeed, many settled villages are of nomad origin because poor nomad families settle into peasant villages when they become impoverished due to the loss of their animals.

Nomads coming from Central Asia came to dominate this region politically from 1000 to 1500 and established a series of important dynasties on the

Iranian and Anatolian Plateaus. These dynasties included the Seljuqs, Ghaznavids, Khwarazm Shahs, Mongol Il-Khans, Timurids, Uzbeks, and Ottomans. From 1500 onward nomads formed powerful regional confederations who retained considerable autonomy until well into the twentieth century. Important nomadic components of such primarily sedentary groups as the Pashtuns, Kurds, and Baluch also existed.

Desert Middle East and North Africa: Camels

The Sahara and Arabian Deserts are home to Bedouins who specialize in raising the dromedary (one-humped) camel for food and transport. They derive other income by extorting dates from oasis farmers, raiding other nomads for camels, selling camels for the caravan trade, and serving as mercenaries. Nomads who only raise camels live mostly in Arabia (the peninsula of southwestern Asia including Saudi Arabia, Yemen, and the Persian Gulf states) and have the widest migration circuits, which allow them to exploit deep desert pastures where only camels can survive because water is so scarce. A larger number of nomads in North Africa and other parts of the Middle East combine camel and sheep raising but have a much more restricted migration cycle because sheep need to be watered regularly.

The camel is a late domesticated (c. 1500 BCE); the nomads who specialized in raising camels emerged in an environment in which the urban civilizations in Mesopotamia and Egypt had already been in existence for two millennia. Camel-raising Bedouins became politically important only after the introduction of the north Arabian camel saddle between 500 and 100 BCE. This saddle allowed camel-mounted warriors to fight more effectively and gave them control of the lucrative incense trade routes that ran through Arabia. Such camel-mounted warriors became the core of the early Islamic armies who conquered the Near East and North Africa during the seventh and eighth centuries.

The rise of camel-raising societies was also facilitated by the growing demand for camels to be used for transport. Camels so effectively replaced wheeled vehicles as the more economical way to move goods that wheeled vehicles completely disappeared from the region until the arrival of cars and trucks during the twentieth century.

Sub-Saharan Savanna: Cattle

Cattle are most highly valued in the savanna areas of sub-Saharan Africa, but goats also play a major role in subsistence, as does seasonal agriculture. In societies in that area ownership of cattle is the key

determinant of a man's wealth and status. Ritual events all demand cattle exchanges or sacrifices. Using huts instead of portable tents, nomads there use only donkeys for transport. Because neighboring sedentary people also value cattle, determining just which societies should be considered true pastoral nomads can be problematic, but in general they have at least a five to one ratio of cattle to people.

The most prominent pastoral nomadic societies live in east Africa and include the Nuer, Turkana, and Masai. The Masai are renowned for a diet that consists primarily of meat, milk, and blood. They expanded rapidly south during the eighteenth century and came to dominate much of the highland grassland areas in Kenya and Tanzania. The Nuer expanded in a similar manner during the mid-nineteenth century in southern Sudan, displacing or incorporating neighboring groups. Broader interactions with the outside world did not occur until the latter part of the nineteenth century when these groups fought to resist their incorporation by European colonial powers. During this period some southern African pastoral societies such as the Zulus rapidly transformed themselves into powerful kingdoms that could more effectively deal with European expansion.

High-Latitude Asia: Reindeer

In high-latitude sub-Arctic areas pastoral nomadism is the most sophisticated variation in a continuum of reindeer exploitation. This continuum ranges from the simple hunting of wild animals, herding semiwild animals for meat harvest alone, to true pastoral nomadism in which domesticated reindeer are milked and used for traction among the Lapps of Scandinavia. Because reindeer feed on lichens rather than the grass or bush species grazed by other domesticated herbivores, societies who raise reindeer are isolated from other pastoralists. As a result these far northern reindeer herders have had the least-direct impact on world history. Although one might suspect that reindeer herding represents the oldest form of pastoralism because societies who depended on hunting

them date back to the foraging (Paleolithic) era, many scholars now believe that the use of domesticated reindeer is historically recent and has emerged only during the past five hundred years.

High-Altitude Asia: Yaks

The high-altitude plateau of Tibet is a harsh environment above 3,000 meters in elevation where the yak makes pastoralism viable. Herds also include yak-cattle hybrids, high-altitude varieties of sheep, cashmere goats, and a few horses. Tibetan pastoralists trade wool, skins, salt, and milk products to valley villagers for barley, which is a mainstay of their diet. In the past they also supplied the overland caravan trade with yak, the only animal capable of carrying heavy loads in that high mountain region. Nomads there move relatively short distances and live in black tents made of yak hair. Many of the pastoral nomadic communities were incorporated into large estates run by Buddhist monasteries until China took direct control of Tibet in 1959.

Political Structures

The complexity of political structures among pastoral nomadic societies is strongly correlated with the degree of centralization found among their sedentary neighbors. The most complex and centralized political organizations emerged among nomads who faced powerful centralized states such as China. By contrast, pastoralists in eastern Africa who faced only other stateless rivals relied on decentralized political organizations. Four basic types existed:

1. Political organization based on age sets among the Masai or acephalous (lacking a governing head or chief) segmentary lineages among the Nuer was characteristic of sub-Saharan Africa, where pastoral nomadic societies encountered few state societies until the colonial era.
2. Political organization based on lineages that had permanent leaders but no overarching or centralized organization

Corn planted us; tamed cattle made us tame. / Thence hut and citadel and kingdom came. • **Richard Wilbur (b. 1921)**

typified North African and Arabian Bedouin societies who encountered only regionally powerful states.

3. Supratribal confederations with powerful hereditary leaders emerged throughout the Iranian and Anatolian plateaus as parts of regional political networks that lay within large empires.
4. Centralized nomadic states ruling over vast areas and vast numbers of people periodically developed on the steppes of Mongolia, usually in response to the unification of China under the rule of a single dynasty.

The centralized nomadic states that formed along China's frontier had the greatest impact on world history. Their combination of horse riding with archery, which created a formidable horse cavalry, made these nomads powerful. Through policies that combined raiding or extorting their sedentary neighbors with controlling international trade networks, these nomads became wealthy and politically influential in spite of their relatively small populations. Such wealth and influence allowed for creation of large, long-lived nomad empires in Mongolia that were the political equals of the powerful native Chinese dynasties with whom they often warred. The most notable of these early empires was that of the Xiongnu, who rivaled the Han dynasty (206 BCE–220 CE) in power. A series of Turkish empires then faced off against the Chinese Sui and Tang dynasties from 581 to 907. In the West the Huns under Attila created a similarly powerful but relatively short-lived empire that threatened the Romans during the fifth century.

The most powerful nomad empire to emerge on the world stage, however, was that of the Mongols. Under Chinggis (Genghis) Khan and his successors during the thirteenth century they conquered most of Eurasia to create a world empire that ran from the Pacific Ocean to the Danube River and from the frozen forests of Siberia to the humid shores of the Persian Gulf. From the eighteenth century onward, however, the steppe nomads' political power declined

significantly because the gunpowder revolution reduced their military advantage. The growing imperial power of czarist Russia in the West and China's Qing dynasty (1644–1911/12) in the East led to the division of the Eurasian steppe between them by the beginning of the nineteenth century and destroyed the autonomy of the steppe tribes.

Pastoral Nomads Today

Although pastoral nomadic societies can be found throughout their traditional ranges, they no longer have the influence they once did. The military power that they wielded as mounted archers or desert warriors disappeared centuries ago. Similarly their ability to remain autonomous by isolating themselves deep in the desert on the steppes or in the mountains was trumped by motorized vehicles and airplanes. As the world's population has expanded, they have lost pasture areas to farmers who have attempted to plow land that is only marginally fit for agriculture. Modern governments that have a bias against people who move and that employ active policies to settle nomads have accelerated this process. Still, in many parts of the world pastoral nomadism remains a viable economic strategy and is likely to continue in some form far into the future. The historical legacy of the nomad remains: the Mongol hordes galloping across the steppe, the Bedouin camel rider topping a sand dune, and the tall Masai holding his long spear are stereotypes so strongly engrained in the popular imagination that we could not eradicate them even if we wanted to.

Paul, Saint

(10–67 CE?)

EARLY CHRISTIAN THEOLOGIAN

More than any other single person, Saint Paul transformed Christianity from a Jewish sect into a world religion. His missionary travels founded churches across Anatolia and Greece; letters to his converts defined doctrine and settled quarrels; and above all, he persuaded Peter and the other apostles in Jerusalem to abandon the Jewish law as a guide to Christian life.

Although he considered himself a Jew throughout his life, Saint Paul is recognized today as the first distinctly Christian theologian. Paul was the first follower of Jesus to insist on the inclusion of Gentiles, or non-Jews, into the family of God. He also was the first to insist upon the importance of Jewish Scripture for the earliest followers of Jesus, and his insistence indirectly helped to form the two-part Christian Bible, which includes the Hebrew Scriptures and the New Testament. His seven authentic letters (Romans, 1–2 Corinthians, Galatians, Philippians, 1 Thessalonians, and Philemon) are the earliest New Testament writings and thus the earliest Christian documents available. These letters are indispensable for any study of the relationship between Jews and Gentiles in the first-century church or any examination of first-century church controversies, doctrines, and practices. In the history of Christianity, Paul's letter to the Romans facilitated Saint Augustine's conversion in the fourth century and Augustine's development of the doctrine of salvation by grace in the fifth century; it buttressed Martin Luther's insistence on salvation by grace through faith alone in the sixteenth century and anchored Karl Barth's work in the neo-Orthodox movement of the twentieth century.

Born a Jew in Tarsus in the early first century CE, Paul persecuted followers of Jesus early in his life. After seeing a vision of the resurrected Jesus, Paul became a follower himself and worked as a missionary between 35 and 60 CE, traveling throughout the ancient Near East and the Mediterranean and establishing churches. The dissonance between Paul's earlier life as a practicing Jew and his new life as a follower of Jesus was not lost on those around him, and Paul had to spend a great deal of time defending his right to be an apostle for Jesus, or a preacher called to spread the gospel (Galatians, 1–2 Corinthians). Paul appears to have been executed as a martyr during the reign (54–68 CE) of the Roman emperor Nero.

Paul's churches consisted mostly of Gentiles, and Paul argued vigorously that Gentiles did not have to adhere to Jewish traditions in order to be considered followers of Jesus. Instead, Jesus' message was available to anyone who believed in his life, death, and resurrection, regardless of ethnicity (Galatians, Romans). Paul also gave instruction regarding the significance of Christian doctrines such as the resurrection and the second coming of Jesus (1–2 Corinthians, 1 Thessalonians). Paul's discussion of the Eucharist, or the Lord's Supper, in 1 Corinthians and the hymn about the Incarnation (the belief that Jesus is both human and divine) in Philippians 2 are the first descriptions of these doctrines. Furthermore, because Paul wrote to specific congregations, he had much to say about social ethics in each of his letters. For example, the status of women in the early church is mentioned in 1 Corinthians, and Philemon may address slavery, although no scholarly consensus exists regarding the exact purpose of the letter.

On his journeys Saint Paul founded churches across Anatolia and Greece.

Paul's legacy remains controversial. While some scholars credit him for the establishment of Christian theology, others accuse him of establishing Christian anti-Judaism because of his occasionally polemical critiques of Jewish practices and his claim that only faith in Jesus, and not adherence to Jewish tradition, makes one righteous before God. His opinions about women and slaves also have been criticized for their apparent support of first-century ideals, which kept both groups in a socially subservient position to free-men. Whether one considers him worthy to be a saint or denounces him as the ringleader of Christian anti-Jewish sentiment and an advocate for social oppression, Paul left his permanent and unmistakable mark on the New Testament and consequently on all forms of Christianity, past and present.

Peace Projects

The goal of a peace project is to establish among states the procedures necessary to settle disputes, and thus to avoid war. Most peace projects take the basic elements that govern civil societies to the interstate level. An analogy between domestic and international frameworks show that the tools used to pacify societies—rule of law, courts, sanctions—may well be applied to interstate relations, and thus be used to pacify the world.

In the depths of World War II, Edith Wynner and Georgia Lloyd published *Searchlight on Peace Plans*, in which they intended to provide insights into peace in a time of suffering and grief. The book summarized the main peace projects and world order proposals drawn up in the Western world since ancient Egypt. Between the fourteenth and the mid-twentieth centuries alone, more than 125 plans have been sketched. Besides many anonymous and obscure authors, some historic figures stand out, such as Dante Alighieri, William Penn, Jeremy Bentham, Immanuel Kant, and Thomas Paine. Well-known and unknown authors all share the same dream of doing away with war.

Peace projects inherently pertain to relations among states, whether these are kingdoms, nations, or modern states. The goal is to obviate war by establishing a set of procedures for the peaceful settlement of disputes. Unlike utopian schemes, peace projects aim at neither changing human nature nor eliminating violence between individuals. However, most peace projects transpose the basic elements that govern civil societies to the interstate level. A very common analogy between

domestic and international structures tends to show that the tools used to pacify societies—rule of law, courts, sanctions—may well be applied to interstate relations, and thus used to pacify the world.

Peace projects are most frequent during and after wars, and even more after particularly destructive conflicts, as F. H. Hinsley, an historian specializing in international relations, observed. They also appear during political turmoil, when entities compete for supremacy. In fact, as one goes through seven centuries of peace projects, one finds that the idea of lasting peace is often tied in with a particular political order. Projects refer as much to the promotion of an order through which peace would be accomplished as to actually fulfilling the dream of a warless world. As the next examples show, what first appears as a scheme for the achievement of a universal aspiration often conceals a particular ideology and specific interests.

From the Middle Ages to the Dawn of the Modern State

The struggle between the papacy and the Holy Roman Empire dominated medieval political thinking. Peace projects reflected this tension. Was the pope a spiritual guide or did his power outshine the emperor's? Both Pierre Dubois (c. 1255–c. 1312) and Dante Alighieri (1265–1321), each of whom wrote a peace project at the beginning of the fourteenth century, took sides against the bishop of Rome. Dante, in *De Monarchia* (1310), favored the emperor. In his hierarchical view of the world, the prince above all princes—the

“Monarch”—was the only one capable of bringing peace to Christendom. In the same way the ancient Roman Empire gave the world the Pax Romana, imperial domination that would bring lasting peace.

Dubois, who wrote under the patronage of the French king Philip IV, adopted a more innovative stance. His work *De Recuperatione Terrae Sanctae* (1305) focused on the Christian crusade to recover the Holy Land. To meet this goal, Dubois claimed that European kings should stop quarreling and renounce warring against each other. Unlike Dante, he opposed the imperial solution on the grounds that Christendom consisted of too many men and too many cultures scattered over too large a territory. Dubois then put forward a new kind of union: a council formed by the sovereigns of Europe that would act as a court of arbitration. Members who refused to submit a dispute or to obey the court’s decisions would then face sanctions, from excommunication to economic and military actions. The pope, in charge of pronouncing the culprit excluded from the Christian community, was left with a moral power. The king of France, on the other hand, would assume the council leadership by executing the sanctions.

Dubois’s scheme was obviously designed to enable Philip IV to encroach upon the powers of the pope and his fellow kings. Peace was at best the second of Dubois’s concerns. Nevertheless, this fourteenth-century plan contained the basic elements of virtually all further peace projects: the formation of a council or a union of independent entities, a set of procedures for settling disputes, and a coercive device.

Dubois’s project fell into oblivion for three hundred years. During that period, the papal dream of temporal power vanished, as did the imperial one of a united Christendom, despite a last attempt in the sixteenth century by Emperor Charles V to revive it. As a reaction to this last imperial endeavor, the European nation-states emerged. Dubois’s text was republished in 1611: his project of a council of sovereign European states, anachronistic in 1310, was now conceivable.

Peace Among Sovereign States

The rise of the modern state system during the sixteenth and seventeenth centuries resulted in a new doctrine, the balance of power. Although based on equipoise, the system saw states continuously struggling to alter the balance for their own benefit. Competition for glory or for economic or territorial superiority—the New World had just been discovered—was an added source of tension. War was an extreme yet lawful means of conducting relations among rival states. Conflicts increased accordingly and, as a byproduct, fostered thoughts on peace. But philosophers were aware that calls for Christian universal brotherhood would fall on deaf ears. They had to follow in Dubois’s footsteps and sketch plans for independent nations to voluntarily join a partnership for the common good. Thus, the peace projects of the seventeenth and eighteenth centuries—Emeric Crucé’s *Nouveau Cynée*, Sully’s *Grand Design*, the Abbé de Saint-Pierre’s *Project to Bring Perpetual Peace in Europe*, William Penn’s *Essay towards the Present and Future Peace of Europe*—are all variations on the same idea. Penn’s and Saint-Pierre’s projects are especially representative of this period. They are, as well, exceptions to the previous assertion that peace plans generally promote specific interests, although they are certainly Eurocentric.

In his 1693 *Essay*, Penn (1644–1718) suggested the creation of a European parliament, which would meet periodically and whose task would be to settle disputes by arbitration and punish aggressive behavior. National representatives would be sent to the “Diet” (the assembly) in proportion to each nation’s power, revenues, exports, and imports. But in return, according to Penn, the member nations would have to abandon the key attribute of national sovereignty—unanimity of decision—within the assembly by accepting a three-fourths majority vote. A nation could thus be compelled to act according to the will of others.

The project proposed by Saint-Pierre (1648–1743), first published in 1712, is based on two observations: firstly, that peace could not be achieved as long as

Masked protestors, symbolizing victims, demand that General Augusto Pinochet be returned to Chile to answer war crimes' charges.

Europe lacked a treaty-enforcing mechanism, and secondly, that the balance of power was a continuous threat to peace. To settle these problems, he suggested the creation of a “grand alliance,” supported by international armed forces. Saint-Pierre, unlike Penn, proposed an equal representation of the twenty-four European states.

For many years, Saint-Pierre sent improved versions of his plan to European sovereigns in the hope that they would realize how they would benefit from organized international relations, adding to his own text objections and counterobjections to overcome any criticism. Like Penn, Saint-Pierre trusted that the European rulers would assess the economic advantages of a peaceful order. But in the 1729 edition of his treaty, the Abbé confessed he had underestimated the essential concern of European leaders, that is, to keep their freedom of action, or what they called their national sovereignty. However much he claimed that preserving the members' independence against an aggressor was precisely the aim of a union, no one

seriously considered it. Saint-Pierre incurred several pungent comments from his contemporaries. Voltaire (1694–1778) scoffed at this “Saint-Pierre of Utopia” who was naive enough to believe that princes, in the name of peace, would abandon precisely that power which defines them. National sovereignty was the stumbling block of peace projects.

The Kantian Approach to Perpetual Peace

Immanuel Kant (1724–1804) was the first to address the inescapable fact of national sovereignty. His *Thoughts on Perpetual Peace* (1795) is the most quoted and influential text on peace. Surprisingly, however, it pertains to the *idea* of lasting peace and not its fulfillment, as Kant's vision of perpetual peace is one of an asymptotic quest: humanity will indefinitely tend toward it.

Kant believed that self-interest was the driving force of mankind. He believed as well that, as much

... they shall beat their swords into plowshares, and their spears into pruning hooks; nation shall not lift up sword against nation, neither shall they learn war any more. • Micah 4:3

as war is inherent to human life, the interest of men lay in submission to the *moral law* of peace. While men perpetually seek to impose their law upon others, they also fear that a law will arbitrarily be imposed upon them. Their only hope of breaking that circle of insecurity is therefore to submit to a common law, a “social contract” of international scope, a federation—in other words, to create a free union of nations instead of a supranational entity that would deny them their identity. Kant, however, stressed one prerequisite for the success of any federal scheme. In the “first definitive article for perpetual peace,” he argued that “the civil constitution in each state should be republican” (1983). Thus, a population which is already governed by a social contract based on a constitution and on the separation of powers is likely to accept its international counterpart. By linking peace and a republican regime—or democracy—this requirement became the cornerstone of the liberal and modern approach to peace.

Kant expressed his views on peace and federalism while the former American colonies were experiencing the first large-scale federal structure. As for Europe, ruled by balance of power, it was sinking into a twenty-year war as a result of the French Revolution and Napoleon’s dream of a new imperial domination.

Peace, Progress, and Interdependence

Major conflicts drastically decreased in Europe after Napoleon’s abdication in 1815, but a quarter of a century of turmoil had greatly stimulated ideas on peace. Peace groups and peace plans flourished in the nineteenth century. The impetus was provided by Quakers who formed the first peace society in 1816. The goals of these various groups were religious—applying Christian principles to national and international relations—as well as humanistic. Inspired by the Enlightenment, they sought to rationalize interstate dealings. As the belief in continuous human progress grew stronger as a consequence of industrial and scientific development, perpetual peace represented the ultimate culmination of civilization.

In the modern world, peace activists believed, war would inexorably become obsolete, and many signs supported this.

Firstly, the “European concert,” even though designed to suppress national emancipation and liberal reforms, showed that leaders could meet during times of tension and find a common solution to European problems. Secondly, the international expansion of trade and commerce made clear the growing interdependence of nations; it seemed as if sovereignty would soon fall into obsolescence. Also, newly founded nongovernmental organizations like the telegraphic and postal unions showed that nations could work together and adopt common rules for the benefit of all. Finally, the popularity of the federal idea in the United States, Switzerland (1848), Canada (1867), and Germany (1871) validated Kant’s prediction that a federation of states (a *Völkerbund*) was a practicable solution, as the first discussion on the “United States of Europe” was held at the 1849 Paris International Peace Congress.

Despite nationalism and armaments, which both grew disproportionately at the end of the century, the belief was strong among peace activists that war would eventually disappear with the help of reason, science, cooperation, and international law supported by arbitration and conciliation. The Great War came as a shock.

Dream of Perpetual Peace in the Contemporary World

Between 1914 and 1918, many peace groups and individuals still produced peace projects, mostly recapping the propositions of the previous schemes (such as a federation of nations, parliament of mankind, international council, and executive force). For their authors, the conflagration made even more obvious the anarchy of the international system and the necessity of rebuilding it on the rule of law. Furthermore, the idea of an international organization for the purpose of preserving peace appeared in political discourse. The pledge by President Woodrow Wilson (1856–1924) to work for a league of peace and his

We make war that we may live in peace. • **Aristides** (fifth century BCE)

call for the expansion of democracy filled peace activists with enthusiasm. Peace projects were no longer purely speculative.

The League of Nations, founded in 1919, tentatively tried to regulate international relations. Carefully designed not to infringe upon its members' sovereignty, its influence, which was solely moral, rapidly faded. As years went by, peace advocates understood that the process of global integration could not come out of such a political structure. The emphasis had to be put on education, cooperation, and the creation of an internationalist state of mind. After World War II, the dream of a peaceful international community continued via the United Nations but, like its predecessor, the U.N. was devised by the victorious countries to reflect the new geopolitical order. Its influence depended on the will of its sovereign constituents.

Kant's reflections on peace still echo today. Two centuries ago, the philosopher warned us against the panacea of a universal structure superseding states. Today, a world federation is still very much premature and universal peace projects are no longer topical. However, the ongoing and peaceful integration of European nations shows that the federal project first discussed in 1849 was not utterly unrealistic. Kant's

call for the extension of the democratic principle and for cosmopolitanism—the international state of mind—may well represent the best hope for peace.

Peacemaking in the Modern Era

Based on the historical record, it is possible to identify a model of peacemaking in the modern era. At the core, peacemaking seeks to ensure equilibrium—no single state should dominate all of its neighbors, and the existence of a dominating nation or group can be balanced by a coalition of states. Peacemaking assures the predominance of the most powerful states while allowing weaker powers to influence international relations.

Theoretically, the French philosopher and political scientist Raymond Aron defines *peace* as the suspension of violence or rivalry between two political units (1966). This process by which two warring powers come to terms and stop fighting can be either imposed by the defeat of one adversary's military forces or, in the case of military stalemate, negotiation aimed at stopping the fighting. Peacemaking is thus the political process by which states shift from the state of armed conflict to the state of peace, theretofore confirming the political, geographic, economic, or social changes imposed by the war.

Related to the birth of the modern international system, peacemaking is associated with the basic principles structuring international relations: sovereignty of the state; the formally recognized equality of the international actors; codification and recognition of international law; and the regulating influence of the balance of power mechanism.

As John J. Mersheimer explains, since states “live in a fundamentally competitive world where they view each other as real, or at least potential, enemies, and they therefore look to gain power at

each other's expense” and, moreover, “have powerful incentives to take advantage of other states,” peacemaking seeks to limit the risk of a new conflict (2003, 52–53).

The Westphalian System

In the seventeenth century, the emergence of the modern state and the rule of law in Europe set the conditions for peacemaking. International relations in the feudal period were based on a vertical power relationship between the European monarchies, the Holy Roman Empire, and the papacy. In such a context, the Holy Roman Empire and the papacy, being the universal representatives of Christianity, could meddle in the internal affairs of European dynasties.

The peace of Westphalia transformed diplomacy by changing the international power relationship to a horizontal one. Based on the four basic principles defining modern international relationships, the Westphalian system introduced the principle of the sovereignty of the state as the basis of interstate relations. More importantly, the two peace treaties that were signed in Münster and Osnabrück in 1648, putting an end to the Thirty Years' War, introduced the concept of national interest as a motivating factor that defined the conditions of peacemaking and resulted in an international system based on a European balance of power. As Henry Kissinger (1957) has shown, European diplomacy was secularized by the replacement of religious motivation with the interests of the state in the conduct of affairs of state. The peace of Westphalia was

Germans participate in a mass demonstration outside the Reichstag to protest the Treaty of Versailles.

based on the introduction of a peacemaking process that preserved the political equilibrium that had arisen from the war that preceded it. In the particular case of the Thirty Years' War, the peacemaking process organized by the king of France, the queen of Sweden, and the Holy German Empire, by its division of the German states, ensured French predominance in continental Europe for the next two hundred years. Furthermore, it showed the way to other peace settlements that ended the numerous European wars waged in the seventeenth and eighteenth centuries.

The Congress of Vienna

The French Revolution and the rise to power of Napoleon Bonaparte (1769–1821) posed a major challenge to the basis of balanced peacemaking. The shift of the political system toward the nation-state system and the introduction of mass armies transformed the basis of peacemaking. By marching on Europe, the Napoleonic armies seemed like an irresistible force challenging the structures of the ancient regime. The conquest of Europe by French armies risked making France the dominating power, putting Britain in league with Austria, and leaving Prussia and Russia to defeat Bonaparte.

The resulting peacemaking agreement was similar to the established diplomatic tradition of the Westphalian system. The Vienna settlement established

Austria, Britain, and Russia as the dominant European powers. When the victorious states met in Vienna in September 1814, the fundamental change behind the peacemaking process was the will of Austria, Britain, and Russia to keep France from regaining its capacity to transform the European balance of power. Napoleon's "hundred days"—when he returned from captivity on the isle of Elba in 1814 and led his troops to a final stand at Waterloo—confirmed the need for a diplomatic system capable of ensuring the continuation of the new balance of power.

Given that the aim of the major powers' representatives (Czar Alexander I of Russia, Klemens von Metternich, foreign minister of Austria, and Robert Stewart Castlereagh, Britain's foreign minister) was to restore the *ancien regime* and limit the impact of the French Revolution on Europe's political system and social values, they understood the need to build a diplomatic system capable of keeping at bay the impact of the Revolution.

With its fundamentally reactionary stance toward the Revolution, the Congress of Vienna, under the leadership of Metternich, adopted a pragmatic approach to the peacemaking process. France was included in the negotiations, the French monarchy was restored but contained by a written constitution, and to limit the risk of antagonizing the French population, the country was allowed to keep its 1789 borders. As a way of controlling France, which had come

Peace is not the product of terror or fear. Peace is not the silence of cemeteries. Peace is not the silent result of violent repression. Peace is dynamism. Peace is generosity. It is a right and it is a duty. • **Oscar Romero (1917–1980)**

out of the Congress of Vienna still a major world power, Alexander I, Holy Roman emperor Francis II, and Frederick William IV of Prussia devised the Holy Alliance. Aimed at ensuring the European status quo, it was shunned by Britain, which considered it too intrusive and conservative. Its first article read as follows:

In conformity with the words of the Holy Scripture which ordain that all men should regard themselves as brothers the three contracting monarchs will live united by the bonds of an indissoluble fraternity, and considering themselves as compatriots will in all cases lend one another assistance, aid and help; regarding themselves in relation to their subjects and armies as fathers of families, they will direct them in the same spirit of fraternity by which they are animated in order to protect religion, peace and justice. (Simpson and Jones 2000, 94)

The main achievement of the Vienna system was to introduce a framework for the collaboration of the victorious powers to ensure the preservation of the European status quo. The result was the congress system, by which Austria, Britain, France, Prussia, and Russia met to respond to and consult with each other on various international crises that threatened the balance of power created in Vienna. Although conservative by nature, the Vienna peace settlement and the congress system that it instituted led to a century of peace that lasted until World War I.

The Treaty of Versailles

World War I drastically changed the European balance of power. The waging of total war led to a peacemaking process that basically excluded the defeated nations from the resulting balance of power to prevent them from seeking to redefine it anew.

The human cost of the war was on such a scale that two new elements were introduced into the peacemaking process that took place at the Palace of Versailles in 1919: war guilt and the establishment of a collective forum aimed at keeping war at bay.

Through its infamous Article 231, the Treaty of Versailles, signed on 28 June 1919, held Germany solely responsible for the war. Excluded from the peace negotiations, Germany was required to pay financial reparations, disarm, and limit the size of its standing army and navy, and it was banned from building a new air force.

Under the influence of U.S. president Woodrow Wilson (1856–1924), the victorious powers accepted the establishment of an international organization designed to ensure by diplomacy and collective security the political status quo resulting from the Versailles settlement. With the aim of legalizing diplomacy by replacing armed conflict with negotiation, the treaty created the League of Nations, an international forum and ancestor to the United Nations. Acting as an international forum aimed at achieving a general disarmament process, it failed under the pressure of the Nazi Germany and Fascist Italy, both seeking to change the balance of power resulting from the war.

Without any authority other than the moral value of its covenant, the league epitomized the failure of the peacemaking process that took place in 1919. The Bolshevik Revolution in Russia and the numerous revolutionary movements in central Europe seemed to pose a real threat in 1919, and the peacemakers had to act with speed to stabilize international relations. But as the historian Jack C. Roth explains, “the defeat of Germany concealed the fact that in 1919 her potential for European domination was possibly greater than it had been in 1914. The war, in fact, ended in such a way as to break up the very coalition needed to keep Germany in check” (1968, 92).

The peacemaking process at Versailles was inspired by a collective will to “legalize” international relations, and the absence of any coercive mechanism meant that the whole system rested on the goodwill of its adherents. Incapable of stopping Japan’s invasion of China in 1931, Germany’s rearmament, or Italy’s invasion of Ethiopia, the League demonstrated the weakness of the collective diplomacy introduced at Versailles and the difficulty of

Blessed are the peacemakers: for they shall be called the children of God. • **Matthew 5:9**

University students in Xi'an, China, flash the peace sign in 1989 following the Tiananmen Square protests in Beijing.

achieving a stable peacemaking process without the use of coercion.

From World War II to the Cold War

The alliance between Britain, the United States and the Soviet Union defeated Germany in 1945. Following a second German bid for power in Europe, the victors decided to build a suitable peacemaking process aimed at ensuring the European status quo. The end of World War II marks a significant shift in international politics. It marks the end of European domination and the emergence of an international system based on the existence of two superpowers: the United States and the Soviet Union.

In Yalta and Potsdam, Britain, the Soviet Union, France, and the United States tried to build a suitable peacemaking process aimed at resolving, once and for all, the German problem. If the United States and the Soviet Union hoped in 1945 to perpetuate their wartime collaboration, their ideological divide soon shattered any hopes of collaboration, and once more the international status quo rested on equilibrium between dominant powers, namely the Soviet Union and the United States. In fact, the incompleteness of the peacemaking process meant that

the world would live under the threat of war for the next fifty years.

The existence of nuclear weapons changed the stakes of international relations. Before the explosion of the atom bomb, war was considered a regulating mechanism reflecting shifts in the international balance of power. With the risk of destroying humanity, the focus shifted from warfare to peacemaking.

Understanding Peacemaking

Based on the historical record, it is possible to identify a model of peacemaking. At the heart of the process, peacemaking seeks to ensure equilibrium so that no single state can dominate all of its neighbors. The existence of a dominating nation or group can be balanced by a coalition of states. Peacemaking assures the predominance of the most powerful states while allowing weaker powers to influence international relations. As long as the interests of the states remain within the boundaries defined by the peacemaking process, the shift to war can be withstood.

Pentecostalism

Pentecostals, who interpret the Bible literally and believe in the imminent return of Christ, are distinguished from other Fundamentalists or Evangelicals by greater exuberance in their religious services. Pentecostals emphasize prophecy, interpretation of tongues, healing, and exorcism of demons. The movement has spread from its roots in the United States to the Caribbean, Latin America, sub-Saharan Africa, Southeast Asia, South Korea, Britain, and Eastern Europe.

Pentecostalism emerged as a distinct movement following the Civil War. It was a radical extension of the Holiness movement that sought to revitalize the Wesleyan doctrine of perfection in various mainstream U.S. denominations, particularly the Methodists. But speaking in tongues (glossolalia), a significant factor in of Pentacostalism, appears to have existed off and on for millennia. Despite a diversity of beliefs among them, Pentecostals generally emphasize (1) the baptism of the Holy Spirit manifested by speaking in tongues; (2) the imminent return of Jesus Christ; and (3) the significance of speaking in tongues as an evangelical mechanism. Although Pentecostals take a literal interpretation of the Bible and stress a puritanical morality, they are distinguished from other Fundamentalists or Evangelicals, such as Southern Baptists and the Churches of Christ, by greater exuberance in their religious services. Pentecostals also emphasize prophecy, interpretation of tongues, healing, and exorcism of demons. At the ideological level, Holiness and Pentecostal sects emphasize the notion of “sanctification.” As opposed to the relatively subdued tone of Holiness services, Pentecostalism

emphasizes inspirational outbursts of ecstasy such as shouting, gesticulating, twitching, fainting, rolling on the floor, and especially speaking in tongues or glossolalia. Some Pentecostal sects in southern Appalachia and the Ozark Mountains even handle poisonous serpents.

Pentecostalism Develops in the United States

Early sites of the Pentecostal movement included a center in western North Carolina and eastern Tennessee connected with A. J. Tomlinson and the Church of God; a center in Topeka, Kansas, associated with Reverend Charles Parham; and the interracial Asuza Street Revival of 1906–1909 in Los Angeles. Parham left the Methodist Episcopal Church to establish Bethel Healing Home in Topeka, Kansas, in 1898. He had been inspired by the healing ministry of J. A. Dowie of Zion City, Illinois, and visited Holiness and healing ministries from Chicago to New York to Georgia in 1900. In late 1900, Parham established the Bethel Bible College in Topeka. Some of his students began to speak in tongues in early 1901 after investigating the doctrine of the “baptism of the Spirit.” Parham closed his school and instructed his students to spread the Pentecostal message. He opened another Bible college in Houston in 1905 and recruited William Seymour, an African American Holiness preacher, who went on to provide the impetus for the famous revival at the Asuza Street Mission. Particularly poor and lower-class people from not only many parts of the United States but also other countries attended the revival. Seymour spread the Pentecostal gospel to both whites and blacks in the Southeast. After

This picture of the U.S. missionary George T. Candlin, who participated in the 1893 Chicago Exposition's World Parliament of Religions (an antecedent of the Pentecostal movement), was accompanied by the caption "This is Pentecost, and behind it is the conversion of the world."

attending the revival with two compatriots in early 1907, Charles H. Mason, one of the two founders of the Church of God in Christ (COGIC), transformed the Holiness sect into a Pentecostal group. His co-founder, C. P. Jones, rejected Pentecostalism and formed the Church of Christ (Holiness) U.S.A. By the early 1910s, the Pentecostal movement had attracted converts in much of the United States, Canada, and northern Mexico with estimates ranging from 50,000 to 100,000 followers.

The initial interracial character of the Pentecostal movement began to break down in the years following the Asuza Street Revival. In 1914, COGIC-ordained white ministers formed the Assemblies of God. Whereas the COGIC, headquartered in Memphis, Tennessee, today constitutes the largest predominantly black Pentecostal group in the

world, the Assemblies of God has evolved, with its present headquarters in Springfield, Missouri, into the largest Pentecostal group in the world. Several years later, Canadian-born Aimee Semple McPherson broke away from the Assemblies to establish her congregation in Los Angeles, which was incorporated in 1927 as the International Church of the Foursquare Gospel. Some Pentecostals, particularly those associated with the Pentecostal Assemblies of the World and the United Pentecostal Church International, emphasized the oneness of God and baptism in the name of Jesus, rather than in the name of the Father, Son, and Holy Ghost. By the end of the twentieth century several hundred Pentecostal sects, many of them African American, had emerged in the United States alone. Both African American and European American Pentecostalism have had a rich history of colorful and even flamboyant evangelists. In the 1940s, Oral Roberts, a Pentecostal Holiness Church evangelist, created a healing and radio ministry based in Tulsa, Oklahoma. "Sweet Daddy" Grace, the founder of the United House of Prayer for All People, functioned as one of the "gods of the black metropolis." Kathryn Kuhlman, a white Presbyterian, and Bishop Ida Robinson, an African American and the founder of the Mt. Sinai Holy Church of America, testified to the ability of women to rise to positions of leadership in the Pentecostal movement, despite the efforts of males to assume dominance. Pentecostal sects also have tended to attract a higher percentage of women than have mainstream denominations.

The Charismatic Movement Develops

While Pentecostalism proper has catered largely to lower-middle- or working-class people, neo-Pentecostalism, or the charismatic movement, has tended on the whole to cater to more affluent people, ranging from the lower-middle class to the upper-middle class. The charismatic movement first spread among some members of mainstream Protestant churches (e.g., Episcopalians, Lutherans, and Presbyterians) in the 1950s and among Roman

Catholics in the 1960s. Demos Shakarian established the Full Gospel Business Men in 1952, and David J. du Plessis, a South African-born Assemblies of God pastor in Connecticut, established connections with mainstream churches by joining the World Council of Churches in 1954 and attending the Vatican II conference as the sole Pentecostal observer. Although the Assemblies of God excommunicated him for these actions in 1962, du Plessis served as an important catalyst in sparking the charismatic movement in mainstream churches. The charismatic movement also received an infusion of energy in the form of the Jesus People movement, a young people's revival that began in California. Jim Bakker, an Assemblies of God minister, and Jimmy Swaggart, also an Assemblies of God minister, joined Oral Roberts as highly visible and influential charismatic televangelists.

The Pentecostal movement within Catholicism began in the spring of 1967 at Duquesne University in Pittsburgh, but later spread to North Dame University and Michigan State University. Although members of the Catholic Pentecostal movement initially called themselves "Pentecostal Catholics" or "Catholic Pentecostals," they later referred to themselves as "Catholic charismatics" for class reasons (McGuire 1982, 4).

Global Diffusion of Pentecostalism

Pentecostalism has spread from its roots in the United States to many other parts of the world, including the Caribbean, Latin America, sub-Saharan Africa, Southeast Asia, South Korea, Britain, and even Eastern Europe. David J. Barrett and Todd M. Johnson (cited in Wacker 2001), renowned statisticians of Christianity, maintain that by 2000 there were 525 million Pentecostals/charismatics (27 percent of the Christian population in the world), which to that date made Pentecostalism the single largest Christian category after Catholicism. Large independent Pentecostal congregations sprang up in large numbers in Latin America and America, particularly during the 1980s and 1990s. Massive conversion to Protestantism, particularly of a Pentecostal variety, has

occurred in Brazil, where various estimates indicate that Protestant churchgoers outnumber Catholic ones on any given Sunday. Many members of Protestant mainstream congregations in Brazil have left in order to establish Pentecostal congregations. Although North Americans introduced Pentecostalism into Latin America, by and large Latinos are now responsible for diffusion of the movement. As in the United States, South African Pentecostalism emerged at the beginning of the twentieth century as a racially integrated movement that attracted blacks and poor Afrikaners and quickly became racially fragmented, in the view of Allan H. Anderson in "Dangerous Memories for South African Pentecostals." (1999). The efforts of various North Americans and Europeans resulted in the formation of the South African District of the Assemblies of God. Many black Pentecostals opted to affiliate themselves with a wide array of African independent sects in South Africa. Some Pentecostals around the globe are interconnected through the Pentecostal World Fellowship, but apparently most are not affiliated with this body.

Interpretations of Pentecostalism

A number of sociologist and religious scholars have written about Pentecostalism as it is now practiced around the world. Robert Mapes Anderson, in *Vision of the Disinherited* (1979), provides perhaps the most insightful analysis of European American Pentecostalism, noting that it serves several functions, none of which seriously challenges the larger society or significantly alters the position of Pentecostals within it. Pentecostalism, he asserts, (1) constitutes a cathartic mechanism for marginalized people; (2) provides career opportunities for its leaders; (3) serves as a "safety valve" for dissatisfaction within mainstream churches; (4) facilitates the migration process from the countryside to the city; (5) instills in its members passivity, industriousness, and thrift; and (6) develops a compliant working class. While the same could be argued historically for African American Pentecostalism as well, an increasing number of black Pentecostal congregations have become more politically and

socially engaged due to the impact of the civil rights and black power movements on a third generation of black Pentecostal ministers. Pentecostal Institutional Temple, COGIC's mother church (located about a mile east of downtown Memphis), played an instrumental role in the establishment of the Ministers and Christians League, an organization that spearheaded a drive that doubled the number of black registered voters in Memphis. Black Pentecostals have won seats on city councils and in state legislatures and have been appointed to minor cabinet positions in the executive branch of the federal government.

Meredith McGuire views the search for empowerment as central to the Catholic charismatic movement. She asserts that even relatively affluent and conservative people in U.S. society "sense that change has 'robbed' them of the power to control the future, to effect their wills on their environment, to know what to expect and to act accordingly" (McGuire 1982, 176). Thomas J. Csordas, in *The Sacred Self*, asserts that the perception of divine presence often instills in Catholic charismatics a sense of security that enables them to overcome memories of traumatic events.

Various scholars have examined the role that Pentecostalism plays in Latin America and other developing and underdeveloped countries. For the most part, Pentecostalism in Brazil and elsewhere in Latin America caters to the poor. Despite the fact that Christian-based communities inspired by liberation theology provided Catholicism with a new lease on life in Latin America, Pentecostalism has proven to be a fierce competitor because of its ability to tap into deeply felt emotional needs and to promise its adherents upward social mobility. Based upon an ethnographic study of Pentecostals in Belem, Brazil, R. Andrew Chestnut, in *Born Again in Brazil*, reports that the great majority of his subjects converted to Pentecostalism during or shortly following a serious sickness. In a similar vein, Thomas R. Lancaster in *Thanks for God and the Revolution* (1988) found that Pentecostal churches in Nicaragua recruit most of their members from the lowest echelon of the poor, many of whom are alcoholics or sick or elderly.

Despite their traditional political fatalism, Pentecostals have also become politically active in Latin America, although they have generally favored conservative candidates such as Rios Montt in Guatemala, a former Pentecostal Sunday School teacher, and Alberto Fujimori in Peru. Indeed, General Augusto Pinochet provided support to Chile's largest Protestant sect, the Pentecostal Church, according to David Stoll in *Is Latin America Turning Protestant?* Some Brazilian Pentecostals have supported left-wing candidates and parties, such as Luiz Inacio Lula da Silva and the Workers' Party. Nevertheless, Chestnut argues that Brazilian Pentecostalism generally "reinforces the political status quo by engaging in the clientelistic politics that predominate in the republic" (1997, 146). South African Pentecostalism for the most part maintained its distance from the antiapartheid movement, although some of the younger black Pentecostals expressed opposition to the regime. In the case of South Korea, Jung asserts that Pentecostalism assumed an explicitly anti-Communist orientation and "produced an ahistorical, apolitical and other-world-centered form of faith" (1999, 151) that served to support the country's capitalist class. Conversely, as Stoll observes, Pentecostal pastors and congregations "tend to retain considerable autonomy in their dealings with state and society" (1990, 319).

An Increasingly Diverse Movement

Pentecostalism, like other religious traditions, is not a monolithic entity. As this essay has indicated, it exhibits tremendous diversity within specific countries, such as the United States or Brazil, and from country to country. At any rate, in the course of a little more than one hundred years, it has become a significant force politically, economically, and culturally. Furthermore, particularly in its charismatic form, it no longer is simply the religion of the downtrodden and disinherited. As a consequence, an increasing number of historians, theologians, sociologists, anthropologists, and other scholars, both Pentecostal and non-Pentecostal, have deemed it a topic to warrant serious consideration with the context of the world-system.

The sociologist David Martin views Pentecostalism, on the one hand, as the Christian equivalent of Islamic fundamentalism in the sense that it constitutes a cultural revolution responding to changes in the large global economy, while, on the other hand, unlike the latter, not offering an overarching political agenda. As a consequence, Pentecostalism, perhaps like Christianity as a whole, may be utilized to support existing sociopolitical and socioeconomic arrangements or to challenge them.

Periodization

History writing, which tries to construct a coherent account of all human societies, requires a structure; periodization, dividing the past into distinct eras, is one technique historians use to create that structure. The technique, however, long involved labeling—the Dark Ages, for instance, or the Renaissance—and thus implied judgments as to the superiority or inferiority of different types of society or different eras of human history.

The past is fluid, complex, and continuous, so any attempt to divide it into neat chronological chunks is bound to be artificial. Nevertheless, history writing, like storytelling, requires a structure, and organizing the past according to distinct eras—a process historians call *periodization*—can help create one. Periodization always does violence to the complex reality of the past, and even the most careful and most honest attempts at dividing up the past involve some distortion. Any scheme must compromise between the often-contradictory demands of clarity, coherence, accuracy, and honesty.

The challenge of finding an appropriate scheme of periodization is particularly complex in world history, which tries to construct a coherent account of the history of all human societies. This article discusses the particular problems that periodization raises in world history, some traditional approaches to periodization, and the compromise solutions that have been adopted as a framework for the *Berkshire Encyclopedia of World History*.

Problems of Periodization

The task of breaking the past into manageable, labeled, chunks of time raises several sorts of problems. We can classify them as theoretical, organizational, and ethical.

Theoretical Problems

Periodization poses theoretical problems because any chronological scheme highlights some aspects of the past and obscures others. While a historian of gender might look for eras in which the relative status and power of women and men changed (the granting of suffrage to women, perhaps, or the emergence of patriarchal social relations in early agrarian societies), a historian of war might be more interested in technological changes that transformed military conflict (such as the use of gunpowder or the appearance of the first organized armies), while a historian of religion might look to the appearance of the so-called universal religions in the first millennium BCE. Different questions highlight different aspects of the past and generate different periodizations. To choose a periodization is to make some critical judgments about what is and what is not most important in human history. By focusing on a particular region, era, or topic, historians can avoid some of these challenges, but in world history, periodization requires judgments as to the most important changes across all societies on earth. Is there sufficient consensus among historians as to what those changes are? At present, the answer is probably no.

Organizational Problems

Periodization also poses severe organizational challenges. How can we find labels that can do justice to many different regions and societies, each with its own distinctive historical trajectory? The problem is peculiarly acute in world history because while neighboring regions or states may evolve in closely related ways, societies separated by large distances may often seem to have little in common. The modern history profession emerged in Europe, and many well-established schemes of periodization were designed to make sense of European history. This is true, for example, of the traditional division into ancient, medieval, and modern periods. Such labels make little sense outside of Europe, but they are so well established that they sometimes get used nevertheless. Similarly, Chinese historians have long used dynastic labels to provide a framework for historical writing, but these, too, are labels that mean little elsewhere. Is it possible to find labels that make sense for Africa as well as for the whole of Eurasia, the Americas, and the Pacific? On this question, too, there is currently no consensus among historians.

Ethical Problems

Periodization also poses ethical problems because it can so easily imply value judgments. School texts on European history have commonly used such labels as “Dark Ages,” “Middle Ages,” “Renaissance,” “Scientific Revolution,” and “Age of the Democratic Revolution.” When used of entire historical periods, such labels were by no means neutral. They were generally used with the clear understanding that the Dark Ages were backward, that the Middle Ages were transitional, and that real progress towards modernity began with the Renaissance. Such schemes carry value judgments about different regions as well as different eras, because they implicitly compare the differing levels of “progress” of different regions. Until recently, it was commonly argued that while Western societies had modernized, many other societies were stuck in earlier historical eras or stages and needed

to catch up. Is it possible to construct a system of periodization that avoids imposing the values of one period or region on another?

No system of periodization can satisfy all these different demands. Like historical writing in general, schemes of periodization reflect the biases and judgments of the era that produced them. They also reflect the questions being asked and the scale on which those questions are posed. This means that no single scheme will be appropriate for the many different scales on which historians can and do write about the past.

Schemes of Periodization

The simplest approach to periodization—one that is present in many creation stories—divides the past into two great eras. These can be thought of as the era of creation and the era of today (as in some Australian Aboriginal accounts), or the eras before and after “the fall” (as in the Genesis story in the Judaeo-Christian-Islamic tradition). Dualistic periodizations offer a powerful way of contrasting the present and the past, either to praise or condemn the contemporary era. Traces of such periodizations survive, even today, in dichotomous schemes such as those of modernization theory, with its stark contrasting of so-called modern and traditional societies.

But most schemes of periodization are more complex, dividing human history into several major eras, each with subdivisions of its own. Dynastic histories weave their accounts of the past using the reign dates of major kings and emperors as their frame. Such accounts are present in Chinese dynastic histories and in the chronologies of Maya historiography. Dynastic histories often imply a cyclical view of the past, in which each era (like each ruler) passes through periods of strength and weakness. Historical accounts conceived within a more linear view of the past often take as their main framework a series of distinct eras, all of which may be seen as part of a larger, universal trajectory. Writing in the eighth century BCE, the Greek poet Hesiod described five great ages of history, beginning with a golden age,

The golden age is before us, not behind us. • **Attributed to
Saint Simon and William Shakespeare (1564–1616)**

in which humans were contented and godlike, and passing through several stages of decline—the ages of silver, bronze, and heroes—and finally to the era of his own day, which Hesiod characterized as one of violence and stupidity.

Patterns of rise and fall have reappeared in more recent writings, such as in the work of Oswald Spengler (1880–1936) or Arnold Toynbee (1889–1975). Marxian historiography offered a combination of cyclical and linear chronologies, beginning with an era of simple perfection (the era of primitive communism), which was followed by stages characterized by increasing productivity and increasing inequality and exploitation. But the Marxist scheme culminated in a future that would resolve these contradictions by combining high productivity with a return to the egalitarianism of the first era.

Most modern attempts at large, synoptic histories have preferred schemes that are fundamentally linear. Such schemes have been greatly influenced by the work of archaeologists and anthropologists, for whom the problem of constructing a periodization covering the whole of human history was often more urgent than it was for historians, who normally focused on shorter periods of time. Because archaeologists, unlike historians, deal mainly with material artifacts, it was natural for them to construct their periodizations around aspects of material culture. The nineteenth-century Danish archaeologists Christian Thomsen (1788–1865) and Jens Worsaae (1821–1885) constructed a scheme comprising three ages—a Stone Age, a Bronze Age, and an Iron Age—that still has some influence within the study of prehistory. In the twentieth century, V. Gordon Childe (1892–1957) built on the Marxist insight that particular technologies imply distinctive lifeways and social structures to argue that the major turning points in human prehistory were the appearance of agriculture (the “Neolithic Revolution”) and the appearance of cities and states (the “Urban Revolution”). Nineteenth-century anthropologists such as Lewis Henry Morgan (1818–1881) and Edward Tylor (1832–1917) offered parallel schemes in which different eras were distinguished by different social

structures in a progressive movement from “savagery” to “barbarism” to “civilization.”

In the late twentieth century, historians, anthropologists, and archaeologists became increasingly sensitive to the dangers of using schemes that imply easy value judgments. So, while most modern schemes of periodization retain a sense of directionality in history, they usually resist the assumption that directionality implies either progress or decline. On the other hand, most modern schemes of periodization at the largest scales still rely primarily on a combination of technological and sociological factors to distinguish between different eras. This is a tradition with roots going back to the earliest written histories. The Sumerian epic of Gilgamesh, which dates from the third millennium BCE, recognizes, in the contrast between the urban warrior hero Gilgamesh and his great friend Enkidu, who came from the wild lands beyond the city, that different technologies imply different ways of living, different systems of ethics, and different types of political and social action. Karl Marx (1818–1883) formalized this insight within the notion of a mode of production. The best justification for such an approach to the challenge of periodization is that fundamental technologies shape so many other aspects of human history, including living standards, demography, gender relations, political structures, and the pace and nature of historical change.

A Periodization for World History as a Whole

The scheme that follows is intended to provide a loose framework for discussing world history at the largest scales. It offers a three-part periodization for human history as a whole, with subordinate periodizations within each of those major periods, which may vary from region to region. This nested structure is, inevitably, an imperfect compromise between various different goals, but it reflects a broad consensus within contemporary writings on world history. At lower levels of generality, articles in this encyclopedia will adopt more specific periodizations that are appropriate for particular questions or regions.

Table 1.
Three Major Eras of World History

Major eras	Approximate Dates (before present [BP] and BCE/CE)	Subordinate Eras	Approximate Dates (before present [BP] and BCE/CE)
<i>The foraging era</i> <i>Societies mainly based on foraging lifeways</i>	250,000–10,000 BP	African origins Global migrations	250,000–100,000 BP 100,000–10,000 BP
<i>The agrarian era</i> <i>Societies mainly based on agrarian lifeways</i>	8000 BCE–1750 CE (10,000–250 BP)	Agrarian communities before cities (later dates outside of Afro-Eurasia) Agrarian communities and the earliest cities and states (later dates outside of Afro-Eurasia) Agriculture, cities, and empires (later dates outside of Afro-Eurasia) Agricultural societies on the eve of the modern revolution	8000–3000 BCE (10,000–5,000 BP) 3000 BCE–500 BCE 500 BCE–1000 CE 1000–1750
<i>The modern era</i> <i>Societies mainly based on modern industrial technologies</i>	1750–today	The Industrial Revolution Twentieth-century crisis The contemporary era	1750–1914 1914–1945 1945–Today

Of the three major eras, the first is by far the longest, lasting for more than 95 percent of the time that humans have lived on Earth, while the modern era is the shortest, lasting just 260 years. On the other hand, populations were small in the foraging era, so that, measured by the number of human lives lived, the agrarian and modern eras loom larger. Perhaps 12 percent of the roughly 100 billion humans who have ever lived, lived during the foraging era, while 68 percent lived in the agrarian era and 20 percent in the modern era. Increasing life expectancies in the modern era mean that, measured by human years lived, the modern era looms even larger, accounting for almost 30 percent of all human years lived, while the agrarian era may have accounted for just over 60 percent and the foraging era for just under 10 percent.

This periodization tackles the central theoretical challenge of world history by taking as its framework three fundamental technological changes. These are the emergence of the first distinctively human societies, all of which relied on foraging for survival, the emergence of agriculture and of societies that depended mainly on

agricultural production, and the emergence of modern, industrial societies. This scheme handles the organizational aspects of all periodization systems moderately well in its first and third eras. Before 10,000 years ago, it is reasonable to argue that all human societies relied on technologies that can be described, loosely, as forms of foraging, so that some useful generalizations can be made about all human societies. But it is also true that foraging societies survived in many parts of the world until modern times, so if we are to define this first era more precisely, we might say that it is the era in which *all* human societies depended on foraging for their survival. In the modern era, too, it is relatively easy to offer a global scheme of periodization because all parts of the world became interconnected and all have been subject to some of the same forces and influences. So we can define the modern era as the era in which the profound technological changes of the last two or three centuries transformed societies throughout the world. The secondary periodization within this era reflects a loose (but by no means universal) consensus on some of the most important transitions within the modern era.

The organizational challenge is most intractable in the agrarian era, from about 10,000 BP to about 250 BP. In this, the era that provides the subject matter for most historical writing, the world was at its most diverse, and no single label can adequately capture that diversity. For most of this era, the histories of Afro-Eurasia, the Americas, and the Pacific world played out in completely separate arenas. While in parts of Eurasia, agricultural societies emerged as early as 10,000 years ago, in Africa and the Americas, all societies relied on foraging for several thousand years more, and in Australia agricultural societies did not exist until the modern era. The best way of defining this era, therefore, is to describe it as the era in which agriculture first began to have a significant impact on human societies in some parts of the world. But the huge differences in timing mean it is vital to opt for flexible subordinate periodizations within this large era. The scheme we have adopted implies the recognition of four broad phases in the history of agrarian societies. These phases occurred at different times in different regions. In the first, there existed agricultural communities, but no true cities and states. In the second, there existed cities and early forms of states and empires. The third phase is distinguished by the emergence of larger and more interconnected systems of cities and states. The fourth phase is defined retrospectively by the understanding that, between 1000 and 1750, the world was on the verge of a transition more revolutionary than any that had occurred in any previous era of human history.

The best way of solving the ethical problems posed by any scheme of periodization is simply to take great care with language and labeling. The labels used here are intended to imply no judgments as to the superiority or inferiority of different types of society or different eras of human history. On the other hand, this periodization clearly does imply a trajectory of some kind. On the largest scales, there can be little

doubt that there is directionality to human history. Foraging, agrarian, and modern societies have not appeared in a chronologically random jumble, but in a clear sequence. And that sequence has an underlying logic that reflects changing human relations with the environment. On large chronological scales, human technologies have changed so as to yield increasing amounts of energy, food, and other resources, which allowed human populations to increase. This, in turn, has given rise to larger and more complex communities, whose technologies and sheer numbers have given them many advantages whenever they came into contact with smaller communities with less productive technologies. There is a shape to human history, and that is precisely why a periodization scheme of some kind is so necessary.

Persian Empire

The creation of the Persian Empire in the sixth century BCE—the largest empire the world had yet seen—brought together two of the four early, major river civilizations (those of the Tigris-Euphrates and Nile). Under the rule of Darius I the empire became highly organized, systematic, and efficient. The empire ended with the defeat of Persian forces by Alexander the Great in 330 BCE.

Cyrus II (c. 585–c. 529 BCE) established the Persian (or Achaemenid) Empire in 550 BCE. It included the Plateau of Iran, northern India, Central Asia, Arabia, Mesopotamia, the Caucasuses, Syria, Palestine, Anatolia (Asian Turkey), Egypt, Nubia, Cyprus, and parts of northern Hellas (Greece). The last Persian king, Darius III (reigned 336–330 BCE) was defeated by Alexander of Macedon (Alexander the Great) in 330 BCE. The Persian Empire brought a period of peace to the areas in its sway for two centuries.

The Rise of the Persians

The Persians were a confederation of tribes who, along with other Iranian-speaking peoples, had moved into the Plateau of Iran in the first millennium BCE. They established their stronghold in such locations as Anshan in the southwestern portion of the plateau, in what came to be known as Persis or Fars Province. Cyrus II was able to unite the Persian tribes by 559 BCE and became king of Anshan. A decade later, in 550 BCE, he was able to defeat the last king of the Medes, Astyages (reigned c. 584–550 BCE). He then moved on to Anatolia

and defeated King Croesus (reigned c. 560–546 BCE) of Lydia, taking his capital, Sardis, in 547–546 BCE. His conquest of Mesopotamia and the city of Babylon in 539 BCE followed. Upon entering, Cyrus honored the Babylonian god Marduk and paid for the rebuilding of the temple of Marduk. He also freed the Hebrews who had been held captive in Babylon and paid for the rebuilding of their temple in Jerusalem, for which the Old Testament remembers him and the Persians kindly (Isaiah 35:40–55; Ezra 1). He left behind a firsthand account in the Akkadian language of his tolerance—the “Cyrus Cylinder.” By the time of his death at the hands of nomadic Saka people around 529 BCE, his empire stretched all the way from the Plateau of Iran to the Mediterranean Sea.

Cyrus’s son, Cambyses II (reigned 529–522 BCE), is known for conquering Egypt and incorporating it into the Persian Empire in 525 BCE. Just as his father had been respectful of the Babylonian deities, Cambyses respected Egyptian ceremonies and religion and was accepted as the pharaoh of the twenty-sixth dynasty of the New Kingdom. From Egypt the Persian forces made inroads into Libya, another force went southward from Egypt toward Ethiopia, and although the Persians were unsuccessful in their military campaign, through negotiations they were able to draw that region into their empire. Upon the death of Cambyses, his brother Bardiya (according to some accounts) or an imposter impersonating Bardiya (according to other accounts) came to the throne. Bardiya—or his impersonator—forgave taxes and initiated land redistribution. It was not long, however, before Darius I (reigned 522–486 BCE), who was married to Cyrus’s daughter, staged a coup d’état with the backing of

the Persian nobility and brought his line of the family into dominance.

Darius I and the Organization of the Empire

Darius is responsible for the organization of the Achaemenid Persian Empire. He unified the empire in many ways. For example, he created a uniform system of measurement and weights throughout the empire for better trade and economic activity; Darius also instituted a unified monetary system; gold coins called *darics* became the recognized coinage in the empire. To govern his unified realm, Darius divided the empire into twenty-three administrative units known as satrapies, each to be overseen by a provincial governor, or satrap.

His public works projects included the building of a royal road, which stretched some 2,560 kilometers from his winter residence in Susa (southwestern Iran) to Sardis; it was just one of the many roads that were constructed in the Achaemenid period. Darius also instituted a postal system along the royal road; through a system of 111 stops and hostels, men and fresh horses transmitted royal decrees and proclamations. Another major public works program was the building of a new capital,

known to the Greeks as Persepolis (City of the Persians). Darius brought together craftsmen, engineers, and materials from all the satrapies to symbolize the coming together of all parts and peoples of the empire. Persepolis was a ceremonial capital, at which during the Persian New Year Darius received guests and ambassadors, who came to pay homage and tribute to the King of Kings. Darius also finished an Egyptian project, the building of a canal in the Suez that connected the Mediterranean to the Red Sea more than two thousand years before the British accomplished the same task in 1866. He then set out to make known to the people under what circumstances he had come to power—his version was that he had wrested the throne from an imposter who was impersonating Bardiya—leaving us a long cuneiform inscription (the Bisitun inscription) in the modern-day province of Kermanshah in northwestern Iran. (That inscription, when deciphered in the 1840s, made possible the translation of Assyrian and Babylonian records.) He then had copies of this inscription translated into different languages of the empire on parchment and leather and sent to the different areas to be read to his subjects.

The Greco-Persian Wars

During the rule of Darius I, the Ionian Greeks revolted against Persian rule and asked aid from the Athenians on the Greek mainland. This action started off the long period of warfare known as the Greco-Persian Wars. Darius's son, Xerxes I (reigned 486–465 BCE) had to retake Egypt, which had revolted, and then set out to conquer Greece in 480 BCE. While he was successful initially, he was later defeated at the battles of Thermopylae, Salamis, and the Plataea. In order to destabilize the Greeks, the Persians then developed the strategy of using the Greek city-state rivalries to their advantage, now supporting one side, now the other. It is important to note that while for the Greeks the battle with the Persians was a threat to their very existence, the Persians thought it not worthy of mentioning in the imperial inscriptions.

Later Achaemenid Rule

The rule of Xerxes ushered in the later part of Achaemenid Persian Empire, during which religious toleration began to wither away. Xerxes I was killed in 465 BCE; he was succeeded by Artaxerxes, who reigned until 424 BCE. He was followed by Darius II (423–404 BCE), and Artaxerxes II, also called Mne-mon (404–359 BCE), who had the longest rule of any Persian ruler.

At this time two important women of the court, Stateira and Parysatis, attempted to exert influence on the king. Artaxerxes II's wife, Atossa, also was to become quite powerful. The reign of Artaxerxes III Ochus (reigned 350–338 BCE) was dominated by the suppression of revolts and the reconquest of Egypt and the conquest of Phoenicia and Cyprus. The last Achaemenid king of kings was Darius III (reigned 336–330 BCE). It was at this time that Philip II of Macedon (reigned 359–336 BCE) conquered the Greek city-states. His military innovations greatly improved the Macedonian (and then Greek) military, and under the command of Alexander of Macedon (Alexander the Great, reigned 336–323 BCE), they became a potent force. Alexander is said to have wanted to take revenge for what the Persians had done in Greece a century earlier. He was able to defeat the Persian forces at three decisive battles at Granicus, Issus, and Gaugamela. Darius III fled to eastern Iran and was murdered there by his own countrymen.

Persian Society

The basic unit of the Persian family was known as *tauma*. Several *taumas* formed a clan, and a conglomeration of clans formed the Persian tribe. At the court the king of kings reigned supreme. An important office below the king was the chiliarch, the go-between for the king of kings and those who wanted to seek an audience with him. Then there were the royal princes who lived at the court who were from the clan. The elite of the Achaemenid Persian society was the Persian and the Median nobility, and royal princes were

An illustration of the four-winged guardian figure, a bas-relief found at Parsargadae, on top of which was inscribed in three languages, "I am Cyrus the king, an Achaemenian."

granted a special position. Part of the warrior class of the Iranians, they were exempt from paying taxes, and many served as commanders of the army and the cavalry. The king possessed a special force, ten thousand men strong, known as the Immortals, dedicated to his protection. These Persian royal princes along with the king were the elite rulers. The royal women lived in the private quarter or harem and were protected by eunuchs. They traveled with the king and the nobility in battle and were allowed to own property.

Slavery was a fact of life. Slaves worked mainly as laborers, both on land as harvesters and as manual workers. However, they were paid for their labor when they were working on the land of the Persian nobility and to a lesser extent on the land of small farmers.

Zoroastrianism (Mazdaism) was the dominant religion of the Persians, and Zoroastrian priests (magi) memorized the sacred hymns and kept the rituals alive. The magi are believed to have been a Median tribe who became the religious doctors of the empire. Darius I mentions the great deity Ahura Mazda more than sixty times in his Bisitun inscription alone. Later on the Iranian deities Mithra and Anahita come to be mentioned and honored by the kings as frequently as Ahura Mazda.

For the most part, the Achaemenid Persians were quite tolerant of other religions. Cyrus II paid homage to the Hebrew god Yaweh and to the Babylonian god Marduk. Economic tablets from Persepolis reveal that the state allotted food for non-Zoroastrian sacrifices. Thus, it appears that although the Achaemenid Persians honored Ahura Mazda at their capital and in their homeland, they did not proselytize.

Significance of the Persian Empire

With the creation of the Persian Empire—the largest empire the world had yet seen—in the sixth century BCE, for the first time two of the four early major river civilizations (those of the Tigris-Euphrates and Nile) were practically unified, and their two civilizations brought into contact with one another. This resulted in the exchange of ideas. It also brought about a period of peace (Pax Persica) in those portions of the world controlled by the Persians for two centuries—something that had not been experienced in the past. Although not remembered fondly by

contemporary Greeks, the Persians are remembered with respect and admiration by contemporary Hebrews and Mesopotamians.

Peter the Great

(1672–1725)
RUSSIAN CZAR

An enduring view in world history of Peter I, czar of Russia from 1682 to 1725, sees him single-handedly transforming Russia from a backward fringe nation into a major modern power, even though some of his policies originated with his predecessors. The epithet “the Great” comes in part from his height; he was 201 centimeters (about 6 feet 7 inches) tall.

Peter I (czar of Russia 1682–1725) was a modernizer who inspired Russia’s rise as a major world power. The son of Czar Alexis I (reigned 1645–1676), Peter ruled jointly with his elder half-brother Ivan until the latter’s death in 1696. During the regency of their sister Sophia (1682–1689), Peter pursued hobbies that informed his later reforms, learning to sail and drilling his “play” regiments. In 1686 Russia joined the Holy League against Turkey and in 1697–1698, seeking aid for that war, Peter became the first Russian ruler to visit western Europe. For Peter it was also a voyage of self-education. His experience of Western cultures prompted him to force his nobles to shave off their beards (attributes of piety for Orthodox Christians) and adopt Western dress.

Following peace with the Turks, in 1700 Peter embarked upon the Great Northern War with Sweden. After early defeats, victory at Poltava in Ukraine in 1709 freed him to capture Sweden’s eastern Baltic ports. In 1711 Russia was defeated by the Turks, but a lenient settlement allowed Peter to pursue the Swedish war to a successful conclusion in the Treaty of Nystad (1721). He accepted the titles Emperor, the Great, and Father of the Fatherland.

War was a determining factor in Peter’s reforms. He improved the army and founded a fleet, using

foreign technical expertise. His goal was to train Russians in new skills and develop private enterprise, but the state remained the chief producer and customer. Peter’s government reforms aimed to improve administrative efficiency. In 1711 he founded the senate, in 1717–1720 new government departments known as colleges, and in the 1700s–1710s organs of provincial government based on Swedish models. To rationalize and improve the military and civil service he created the Table of Ranks (1722), comprising a ladder of fourteen grades. Men from the hereditary elite continued to enjoy prominence, although some newcomers made their fortunes, most famously Peter’s favorite, Aleksandr Menshikov (c. 1670–1729).

Peter successfully established technical schools, such as the Moscow School of Mathematics and Navigation (1701), but new elementary schools (1714) generally failed to attract pupils. The Academy of Sciences (founded 1725), initially staffed entirely by foreigners, was his major achievement in this field. The Orthodox Church also ran schools. In 1721 Peter replaced the patriarchate (the last patriarch died in 1700) with a state-monitored committee of clergymen called the Holy Synod to run the church. He restricted entry into monasteries and requisitioned church funds for the war effort.

In 1703 Peter founded Saint Petersburg on former Swedish territory, as a base for the Baltic fleet and a port for foreign trade. From about 1712 it replaced Moscow as the capital. Saint Petersburg became Russia’s “window on Europe.” Its main buildings were designed by foreign architects and its inhabitants had to follow European fashions. In the seventeenth century upper-class Russian women had lived in

Paul Delaroche, *Peter the Great of Russia* (1838). Oil on canvas. Lenin and Stalin admired Peter for “accelerating” Russia’s economic and military development.

semi-seclusion; Peter now forced them to socialize with men. Many Russians, however, resented being uprooted from Moscow to these alien surroundings.

Peter was a practical man. He studied many crafts, including ship building, woodturning, and dentistry. He began his army and naval careers from the lowest ranks as an example to others. But this man with a common touch remained an absolute ruler with an ambitious vision: to make Russia the equal of other European nations and to win their respect. He faced serious problems. More than 90 percent of his subjects were peasants and half of these were serfs. Peter had to extend and intensify serfdom to meet the demand for army recruits, labor, and tax revenues. The nobles, too, found lifelong service burdensome. They had no corporate rights or institutions and they were subject to Peter’s numerous regulations, devised “in order that everyone knows his duties and no-one excuses himself on the grounds of ignorance”—as it was stated in many edicts. These principles extended to Peter’s heir, Alexis Petrovich (1690–1718), the son from his first marriage. Alexis opposed many of his father’s ideas and in 1718 he was condemned to death for treason. In 1722 Peter duly issued a law that required the reigning monarch to nominate an heir, to reduce the risk of an “unworthy” successor. But Peter failed to make a nomination. He was succeeded by his widow, Catherine I (reigned 1725–1727), a Livonian peasant whom he married in 1712.

An enduring view of Peter the Great is that he single-handedly transformed Russia from a backward fringe nation into a major modern power, even though some of his policies originated with his predecessors. At 201 centimeters tall, he was larger than life. Both Lenin and Stalin admired Peter for “accelerating” Russia’s economic and military development. Opinions are divided about the “bal-

ance sheet” of his activities, however. Critics question the heavy cost of his schemes, his use of force, the dangers of excessive imitation, and the split he created between a westernized elite and the peasant masses. He remains a controversial figure in Russia today.

Philosophy, Asian

Finding harmony with others and harmony with nature are foundational goals of Asian philosophies. While Indian traditions (Hinduism, Buddhism, and Jainism) focus largely on the individual's path toward harmony with the cosmos, Chinese philosophies (Confucianism and Daoism) depend on finding the right Way (*dao*) to live a prosperous life—and on worthy rulers to administer the state in line with the right values.

Asian philosophies teach notions related to living well in harmony with others and in harmony with nature. Both India and China developed complex responses to issues of cosmology, ultimate meaning, ethics, and human will. Especially today, Asians are seeking to reclaim their philosophical foundations, and intellectuals worldwide see the need to understand traditional and contemporary Asian thought. In south Asia, the profound affect of Mohandas Gandhi's teachings on nonviolence can still be seen. In China, the twenty-first century has seen a resurgence of interest in neo-Confucianism. Understanding the key ideas of Hinduism, Buddhism, Jainism, Confucianism, and Daoism can help put the role of India and China on the world stage in a clearer context.

From the creations myths conveyed in the hymns of the sacred Rig Veda some 3,500 years ago, to the emergence of the Jainism (800 BCE) and Buddhism (500 BCE), and, in the early centuries of the common era, the six distinct paths toward spiritual realization, philosophies originating in India grew from and fostered a number of beliefs: the connectedness between the human order and the larger cosmos; principles of self-sacrifice as a means of fulfillment; the importance

of breath and breathing techniques; the theory of karma (the law of moral causation); hierarchical relationships, rules, and rituals that bring an individual to a place of identification with and empathy for the natural order; and methods of achieving transcendence and interiority. Indian philosophy, then, was largely focused on an individual's path toward harmony with the cosmos.

Ancient Chinese philosophy focused on finding the Way (*dao*), that is, the right way to live a prosperous life. Unlike Greek and Roman philosophers who sought an abstract truth, Chinese philosophers sought the best path to success. The Chinese philosophical tendency inspired a social movement away from aristocratic birth rights to follow worthy rulers with versatile ministers who could administer the state, ensuring safety and a good harvest. The ancient Chinese developed logical argumentation, made scientific discoveries, and invented technology, especially in metallurgy and agriculture, that required a greater need for (and advanced as a result of) these philosophical "disciplines."

Ancient Indian Thought

The philosophy of India begins with the early hymns of the Rig Veda. Chanted, memorized, and kept sacred by priests whose ancestors composed them at least 3,500 year ago, in the northern area of what today is Pakistan and India, these hymns represent the oldest extant literature in the Indo-European language family.

In the creation narrative of the Rig Veda (X: 129), the world begins in a nameless, shapeless chaos. From this beginning, water first emerges, followed by the

Prince Siddhartha cuts his hair, signifying his retreat from the world. Relief sculpture at Borobudur. New York Public Library.

fire of the sun and the movement of breath. Desire wells up from these vaguely perceptible entities, and from desire, that which is below distinguishes itself from what lies above. Sages emerge who perceive that the existent always remains in close proximity to the non-existent. They also proclaim that no one can look to the gods for answers on the ultimate origin of the universe, as the gods were created after that originary moment.

In another hymn, the human body is seen as a microphase of the macrophase realities of heaven and Earth. Human feet touch the body of the Earth. The mid-regions of the body correlate to the rise and fall of the breath. The head reaches up into the sky, with the right eye betokening the sun and the left eye the moon. Furthermore, human social structures also follow the structures of the body. Farmers work the Earth and correlate to the feet. Merchants ply their wares through the movements of the legs. Soldiers and kings protect the people with their strong arms. Priests, teachers, physicians, and law-givers depend on their heads in order to maintain ritual order.

The story of the great warrior Indra, who battles the life-obscurer dragon to release life-giving waters (and hence ensures the flourishing of humans), also embodies early Indian philosophy. From the dreaded, drought-filled state of non-existence (*asat*), Indra allows the emergence of a reliable existent realm or world (*sat-loka*) by releasing the life-giving monsoons with his thunderbolts (*vajra*). Within this realm, people are free to perform sacrifices (*yajna*) to myriad deities, seeking fulfillment through worship of Lakshmi to receive wealth, Sarasvati to receive knowledge, Vak to become strong in voice, and so forth. Having sacrificed and been fulfilled, one dwells for a moment in a state of art, ritual culmination, and

rhythm (*ṛta*) that signals the good life. Eventually, the cycles of life continue, requiring the process again to repeat.

Foundational Traditions

When they emerged by 800 BCE, the early Upanishads (spiritual treatises) signaled new philosophies that form the foundation for later traditions. Desire and the importance of the breath remain constant themes. New insights given forth by such teachers as Yajñavalkya and Satyakama Jabala discuss the primacy of the elements and the importance of orienting oneself within the four directions, the three zones—Earth (*bhu*), the atmospheric zone of life and movement (*bhuvā*), and the sky above (*sva*)—as well as the vast ocean (*udaka*). Yoga, reincarnation, and ideas of karma were first introduced into Brahmanical circles through the Upanishads.

This same historical period saw the rise of Jainism (c. 800 BCE) and later of Buddhism (c. 500 BCE). The Jainas emphasized a rigorous code of ethics designed to rid the human spirit (*jiva*) of the fettering presence of karmic material. This code includes the practice of nonviolence, truthfulness, not stealing, sexual restraint, and the minimal possession of material goods. The early Jainas condemned the elaborate animal sacrifices performed by some Brahmanical communities, and continue to promote vegetarianism.

Siddhartha Gautama (Buddha, c. 566–486 BCE) created a monastic religious order more moderate than that pursued by the Jainas. The Buddha taught an eightfold path to rid oneself of suffering, beginning with the adoption of right view and culminating in rarefied states of meditation. Both traditions created copious literature, detailing their philosophy (purification of soul in Jainism, absence of enduring soul in

Krishna sits on a white snake with a woman who washes his feet. A deity rises above in a lotus flower. From an 1850 version of the *Mahabharata*. Beinecke Rare Books and Manuscript Library, Yale University.

Buddhism), the stories of their great teachers, past life narratives, and detailed lists of rules to be followed.

In the Brahmanical traditions, four goals and an ideal fourfold analysis of life stages emerged. Dharmashastras (Hindus law codes, both sacred and secular, written between 600 and 300 BCE) list the pursuit of wealth and pleasure as the first two great necessities. Next is the responsibility to society (*dharma*). For some, these three goals provide insufficient meaning for human life. In such a case, there is a fourth: the quest for liberation (*moksha*) by following a teacher (*guru*) skilled in techniques and philosophies that lead to transcendence. At the

age of seven, according to the ancient Dharmashastras, one's study should begin and continue for approximately seven years, after which one marries and takes up the life of a householder. In late middle age, one might turn all one's duties to one's children and grandchildren and enter the stage of the spiritual quest (*sannyasa*). Those who gain wisdom then are qualified to teach others.

Six Distinct Paths

By the early centuries of the common era, six distinct philosophical paths arose within Brahmanical India: Samkhya, Vedanta, Yoga, Nyaya, Vaisheshika, and Mimamsa. The first three hold forth spiritual attainment as a human possibility. The last three claim that liberation from the woes of the world can only take place after death. The best hope, according to these three, is to live one's life well, with hopes for reward after death.

Classical Samkhya analyzes life in terms of two major categories, consciousness and activity, with the latter divided into twenty-three subcategories. Activity generates a psyche that differentiates into ego and thought. This psyche, which serves as the repository for karma, can be fraught with anxiety and difficulty, or it can be trained to become pure. The psyche further gives forth the human body, whose action organs (anus, genitals, hands, feet, and voice) are connected to the five senses and to the five elements of earth, water, fire, air, and space. By understanding that all this activity provides experience and liberation for consciousness, one advances toward human freedom.

Vedanta, while not rejecting the details provided by Samkhya, opts for a simpler philosophy. Grounded in some of the great apothegms from the Upanishads, Vedanta proclaims that all things are suffused with an indwelling consciousness linked to God. God is one without a second. All things are part of God. Each individual embodies that God in the form of an individual soul (*atman*). When one sees the true nature of one's soul, then a connection is made with God.

Yoga, building on Samkhya, provides specific ethical and physical practices to move an individual to a state of freedom (*nirbija* or *dharma-megha samadhi*; also referred to as sublime aloneness or *kaivalyam*). These include the cultivation of friendliness, compassion, happiness, and equanimity, as well as the ethical precepts of the Jainas listed above. The Yoga sutras of Patanjali specify the performance of exercises to purify the breath and make connection with the energy centers of the subtle body (chakras).

To live the good life, Nyaya suggests that one be skilled in thought and logic. Vaishesika outlines the categories of the physical world, suggesting that by knowing how the world works, one can optimize pleasure and happiness. Mimamsa provides detailed instructions for how best to perform rituals, noting that an act of worship yields states of deep happiness.

By the late classical period (c. 400 CE) these various traditions were in active conversation with one another. The Buddhists constructed a vast university near modern-day Patna called Nalanda, which housed and trained thousands of monks each year. By this time, vast temple and cave projects gave testimony to the wealth and power of each of these three traditions, Buddhism, Jainism, and what came in later years to be known as Hinduism. Epic literature, including the *Mahabharata*, the *Ramayana*, and the *Puranas* became widespread. These vast texts, in addition to including compelling stories, also served as a vehicle for people to learn about philosophy. The *Bhagavad Gita* emerged as a repository for the teaching of Indian thought, as Krishna (an avatar of Vishnu) informs the reluctant soldier Arjuna about Yoga in its various forms: Knowledge, Action, Devotion, and Meditation.

New Visions

In the seventh and eighth centuries a new movement appeared, Tantra, which arose in both the north and the south. Tantra suggested that rituals might be enacted that would efficiently propel one toward deeper states of power and interiority. It included the violation of conventional morality in order to help

practitioners overcome all forms of attachment. Tantra gave birth to a copious new body of literature, both Hindu and Buddhist, as well as stern critiques of its methods by numerous Jaina monks, for whom the adherence to a strict ethical code was inviolable.

At the same time the young philosopher Sankara, who wrote extensive commentaries on the Upanishads and the *Bhagavad Gita*, advanced a new philosophical articulation known as Advaita Vedanta. Sankara emphasized that the world of change is merely an illusion (*maya*) and that through correct contemplation and remembrance of “not this, not that,” one can sift through the veils and dross and achieve a vision of reality. Other philosophers came to prominence over the next several hundred years, including Abhinavagupta, who articulated a philosophy grounded in aesthetics, and the unnamed author of the *Yogavasishta*, who advanced a view that the world appears and dissolves as if it were a dream, and that we need to find the strength within to manage and purify this dream. Partly in response to the compelling monotheistic theology of Islam, which began to enter India by the eleventh century, devotional movements arose that urge dedication to a single deity, most notably Krishna, particularly as found in the poetry and song of Chaitanya and Mirabai. The middle period of the last millennium also saw the rise of systematic philosophers such as Yashovijaya (Jaina) and Vijnanabhikshu (Advaitin). By this time, Buddhism had retreated from India as the Sultans from the west destroyed Buddhist monasteries and libraries. Hindu and Jaina construction projects were dwarfed by such edifices as the Taj Mahal.

The British period of India saw a resurgence and re-energization of Indian thought. Such thinkers as Ram Mohan Roy, Swami Vivekananda, Rabindranath Tagore, Sri Aurobindo, and Mohandas (Mahatma) Gandhi received Western educations and brought new ideas into dialogue with the ancient texts and traditions of India. Roy was an advocate of a Hindu Universalism. Vivekananda suggested that the Yogas of India would enhance spirituality worldwide. Tagore, a Nobel Laureate, reminded the world of the importance of poetic beauty. Aurobindo rejoiced in

... bearing with the uncultured in gentleness, / fording the river with resolution, / not neglecting what is distant, / not regarding one's companions: / thus one may manage to walk in the middle. • *I Ching*

joining such ideas as evolution with the inner process of self-realization. Gandhi's philosophy of nonviolence revolutionized political strategies. Not only did he successfully campaign for India's independence from colonial rule, he also inspired the civil rights movement in the United States, and the overthrow of Marcos in the Philippines decades later.

Philosophy in India has a long legacy. As the world modernizes, its distinctive stamp can be found not only in the subcontinent, but also in a now nearly universal discourse on theories of karma, dharma, and the life well lived through various forms of Yoga.

Ancient Chinese Thought

Before the state of Qin unified China in 221 BCE, ending the bloody Warring States period (475–221 BCE), Chinese philosophers focused on finding the right Way (*dao*) to pursue a prosperous life, and they expected rulers to administer their governments according to those values. The various philosophers of the pre-Qin period were subsequently categorized into schools of thought. Sima Qian's (145–86? BCE) *Records of the Grand Historian* (c. 99–98 BCE) lists six schools: Confucian, Mohists, Legalists, School of Names, Yinyang School, and Daoists. In Ban Gu's (32–92 BCE) *Standard History of the Former Han*, the "Journal of Literature" by Liu Xin (d. 23 BCE) adds four schools: Agriculturalists, Diplomats, Eclectic School, and Storytellers. Each "school" contains interpretations that are used to subdivide them. There are various sub-schools of Confucianism, Mohism, and Daoism, as well as schools not listed in these ancient records, including the Militarists School, and the Pacifists represented by Song Rongzi. Unsurprisingly, disputes materialized not only about which way (*dao*) was right way, but about how to find it.

Technological changes in agriculture, metallurgy, military arts, and rulership created the need for skilled personnel. The notion of a worthy ruler leading versatile ministers is a shared idea among the various philosophers. Political, economic and cultural changes accelerated during the pre-Qin period, opening a context for new philosophies. Providing

an education for everyone, even commoners, begun by Confucius (551–479 BCE), became popular during the pre-Qin period because of the need for highly trained scholar-knights, officials, and skilled craftsmen. Most of the pre-Qin philosophers proposed that all people, especially the ruler and ministers, adhere to their socially acquired roles. Everyone was to do his or her part for society to function properly. Most of the philosophers looked back to a past golden age to set a standard for harmony among people and with nature. Many of them advocated that everyone is potentially a sage. Aside from these general commonalities, the various philosophers disagreed about the details for achieving harmony and how to properly educate people.

Confucius and His Influence

Confucius believed that the Zhou imperial family and the feudal lords had lost the way of the former kings, the way of the Zhou founders—kings Wen and Wu, and the Duke of Zhou. For Confucius, the *dao* refers to the way of the former kings, the way of virtue. Confucius advocated the popular idea of a past golden age of perfect social harmony. He intended to reform society by reviving past virtues and values; such reform instituted first within the ruling families, would trickle down to commoners through aristocrats. Methodologically, Confucius' teachings begin by instilling filial piety within children. Filial children become loyal ministers. Ontologically, Confucius held that all people are similar at birth, having the ability to be kind. Through improper training, people lose their natural propensity to be kind. Filial devotion maintains the propensity to be benevolent. These teachings promote graded love in which people love close relatives more than distant ones and villagers more than strangers.

The problem of social decay is further abated by virtue education and character development. Ritual action (*li*) is the proper way to promote human kindness (*ren*). All people and especially government officials must be trustworthy (*xin*). People must follow the correct standards of rightness (*yi*). They should

practice moral wisdom (*zhi*). These are commonly called the five virtues; there are many more. Through virtue education people learn their role and practice virtue, resulting in a well-rounded individual and peace in the empire.

The Confucian disciples emphasized different aspects of his teachings. Mencius (Mengzi, 371–289 BCE) argued that people are naturally good at birth. Mencius interpreted the Mandate of Heaven, the divine sanction to rule, to include peasant rebellions. Mencius debated against the individualist Yang Zhu, the Agriculturalists, the Militarists, and the Mohists. His philosophy was revitalized in Song dynasty (960–1279 CE) Neo-Confucianism. Xunzi (fl. 298–238 BCE), who offered a pragmatic Confucianism, proposed that people are born deviant. Education and ritual-action control them. Xunzi argued that a wise ruler follows the way of the recent kings, not the former kings. His teachings influenced the development of Confucianism in the Han dynasty (206 BCE–220 CE).

Mozi (Mo Di, fl. 479–438 BCE) began as a Confucian. Trained in military arts, he defended the underdog. He attracted many disciples. Like Confucius, Mozi believed that the way of the former kings and virtue education are the means to rectify social decay. He attacked Confucius' project. For Mozi, social decay is caused by promoting the family values and graded love of Confucius. Mozi argues that the way of the former kings promotes equal love for each and every person (*jianai*). If people would love each other the way they love their parents, all strife would end with peace in the empire. For the general welfare, Mozi advocated frugality in state functions, opposing the excesses of aristocratic funerals and musical performances that the commons imitated. Mozi criticized offensive warfare as evidence that graded love generates misery. His followers developed methods for defining terms and argumentation.

The Legalists argued for social reform to establish law and order, proposing that Confucianism and Mohism corrupt society by promoting morality over the law. Morality creates social problems because it justified protecting special interests, not the law. As the Western Zhou (1045–771 BCE) incorporated various

ethnic groups and expanded economically, the need for legal governance grew. By the end of the Spring and Autumn period (770–476 BCE) written laws were published. Some Legalists emphasized the need for a well-ordered state administration; written law applied equally to commoners and nobility, the value of statecraft, and political techniques and methods. Han Fei and Li Si studied under the Confucian, Xunzi. They went to Qin to assist Lü Buwei, prime minister to the child king who would become the first Qin Emperor. Han Fei synthesizes Legalist thought, especially the concepts of law, power, and statecraft. He attacks the Confucians and Mohists for claiming to accurately represent the moral way of the early sage rulers, criticizing their morality in favor of the law. Similar legal developments occurred in the ancient Greek and Roman states.

The School of Names (or Logicians) originated among the officials who allocated rewards and punishments. Assessing job titles and performance transformed into a philosophy of linking name and reality. Because debate was the means by which philosophers gained fame and a livelihood, argumentation was emphasized by all the schools. The logicians took rational inquiry into the paradoxical realm. Hui Shi (c. 380–305 BCE) was a friend of the Daoist Zhuangzi. They argued that all things form a comprehensive unity. Hui sought to know that unity through reason and language. Zhuangzi sought it through direct experience. Their ideas can be contrasted with the Greek Skeptics and Sophists.

Grappling with nature's forces, people demarcate bipolar, interconnected yet opposing phenomena, such as heavy/light, dry/damp, hot/cold, bright/dark. This kind of correlative thinking underlies most Chinese philosophy. It is seen in the Greek pre-Socratic thinkers, especially Anaxagoras. At first, yin denoted the shadow, and yang the sunlight. Later they become philosophical concepts, referring to the interconnected yet opposing forces of the universe. Yang is associated with light, movement, the male gender, and life-giving forces. Yin is associated with darkness, tranquility, the female, decay and death. These two forces are interconnected and contain each

other. They are used to explain why and how things change. They were coupled with the five phases (*wuxing*), namely, wood, fire, earth, metal, and water.

Daoists and the Way

If the Confucians establish the cultural tradition, then the Daoists form the counter-culture. Unlike most philosophers, the Daoists wanted to be anonymous. Some of their ideas are similar to those of Heraclitus. Some of the Daoist practices are similar to the Greek Cynics who withdrew from society. Their meditation practices can be compared to Hindu and Buddhist practices. Daoism originates in ancient shaman-practices such as merging with the forces of nature. These shamanic practices were modified into breathing and meditative techniques (Roth, 1999).

The *Laozi* and the *Zhuangzi* are the two extant texts from the pre-Qin period that form Daoism's core. Lao Dan or Master Lao (Laozi, c. 6th century BCE), is the alleged author of eighty-one poems (chapters) that bear his name, *Laozi*. The text was written by court officials who sought to give advice to their ruler and other officials on the proper way to govern the state by means of self-cultivation that connects them to the forces of nature. The four great things in existence are: the *dao*, sky, Earth, and the king. People take Earth as their model; Earth follows sky; sky follows *dao*, and *dao* follows self-so-spontaneity (Laozi, chapter 25). The ruler is encouraged to behave like the *dao* by taking no purposive action and nothing will be left undone (Laozi, chapter 37). Laozi's contribution to ancient philosophy was his ability to abstract the *dao* into the most general and ultimate category.

According to Zhuang Zhou's (370–301 BCE) biography in the Records of the... Historian, he rejected an invitation by King Wei of Chu (reigned 339–329 BCE) to serve as prime minister. He is the alleged author of the first seven chapters of his namesake book, the *Zhuangzi*, focusing on the theme of self-cultivation by embracing the flow of natural transformation that ultimately leads to entering the silent oneness of the sky, or mystical union with the *dao*. This type of nature

The yin–yang and *bagua* symbols are both significant to the philosophy of Daoism.

mysticism can be contrasted with the transcendental mysticism of the Neoplatonists and Brahmanic mysticism. Living properly in harmony with the forces of nature, the *dao*, and dying in harmony with nature is the ultimate mystical experience. Zhuangzi's philosophy emphasizes the importance of living in harmony with change. Zhuangzi recognizes that people are preoccupied with others' opinions. So they work hard, live in distress, and die young. He proposes that people practice meditation and reduce stress and conflict to bring them into harmony with the *dao* of nature.

The first three texts, the *Shizi*, the *Lüshi chunqiu*, and the *Huainanzi*, listed under Eclectic School in the "Journal of Literature," are philosophical works that employ a unified philosophy, drawing from the other schools. The *Shizi* (c. 300 BCE), survives in fragments, synthesizes other philosophies. The syncretic, unified philosophy of the *Lüshi chunqiu* (238 BCE), and the *Huainanzi* (130 BCE) are more obvious. The *Lüshi chunqiu* organizes the philosophical systems under the seasonal calendar such that Yang Zhu's individualism, Daoist non-action, and Mohist love are practiced in the spring; Confucian education, ritual, and music are studied in the summer; military and legal affairs are reserved for the autumn, and Mohist frugal funerals, Legalist administrative matters, and executions are suited for the

winter. This eclectic trend influenced Han dynasty literature and philosophy.

The Militarists are not listed among the other schools in the Han histories. They were given the honorary title of Master (*zi*) that is bestowed on the philosophers. Sun Wu (Sunzi) is famous for his work on strategy, the *Art of War*, which is studied at military academies today. His text recognizes the importance of developing moral virtues in the troops to bolster their loyalty, and proposes only engaging in just war.

The pre-Qin period was a turbulent yet important time for Chinese philosophy. Aspects of the various schools were absorbed into Han dynasty Confucianism, making it comprehensive and viable. Although Confucians disdain Legalism, the imperial “Confucian” state sponsored by the Han and subsequent dynasties could not have prospered without a legal system, first and foremost, in addition to the system of ritual for controlling the masses, and for diplomacy with other countries. Given the eclectic character of the subsequent development of Confucianism and Daoism, the Eclectic school left a lasting impression on Chinese philosophers as they continued their search for the right Way.

Philosophy, Greek and Roman

Greek and Roman philosophy evolved in the ancient world amidst inquiry about the nature of reality and the relationship between reason and emotion. Plato and his student Aristotle (and their disagreement about Plato's Theory of Forms) are perhaps most recognizable in the modern world, but the claim of Heraclitus (fl. 510–490 BCE)—that wisdom is gained by understanding how reason guides the world—characterizes all subsequent Western philosophical thought.

Philosophy, derived from the Greek “love of wisdom,” is the rational inquiry into the truths and principles of existence, knowledge, and ethics. It includes cosmology, natural history, ethics, epistemology, and politics. The root of Western intellectual heritage, Greek and Roman philosophy developed in an atmosphere of contentious debate, and investigated key intellectual questions: the nature of reality; and relationships between logic and reality, knowledge and skepticism, reason and emotion. Most original writings are lost; of the Greeks, only Plato's and Aristotle's survive. Most Greek philosophy is at best partially reconstructible from later, often hostile, writers whose brief extracts usually lack context.

Pre-Socratic

Early Greek philosophy, labeled “Pre-Socratic” despite the inclusion of thinkers contemporary with Socrates, originated circa 600 BCE in Miletus in Ionia (Turkey), a wealthy Greek port town where thinkers encountered Near Eastern innovations in medicine, agriculture, mathematics, and astronomy. This contact

inspired Milesian philosophers to ask new questions about the world. What are the ingredients, composition, and operation of the natural world? Is *phusis* (nature) one thing or many? What is the process of change whereby things come into being, pass away, and are transformed from one thing to another? Eschewing magic, gods, and the personification of nature, philosophers explained existence according to observable principles in nature. Three Milesian material monists—monism puts forth the belief that one fundamental substance is the *archē* (original source) of all existing matter—offered slightly differing interpretations. Thales (fl. 600–545 BCE) theorized water as his *archē*, perhaps from observing the generative nature of moisture (seeds require water to germinate). Anaximander (fl. 580–545 BCE), believing that water was too specific, proposed a substance containing all the opposites, thicker than fire but finer than air, indestructible, indeterminate, intermediate, infinite—to *apeirōn* (the boundless). Anaximander, hypothesizing a mechanism to explain how matter interacts, significantly suggested that material objects are separated from *to apeirōn* through condensation and rarefaction. Anaximander's pupil Anaximenes (fl. 555–535 BCE), who posited air as his *archē* but retained Anaximander's principle of condensation and rarefaction, adapted this paradigm of a unified theory of matter and energy. The monists (rightly) believed matter cannot be created or destroyed, only altered.

Heraclitus of Ephesus (fl. 510–490 BCE) shifted the focus of Greek philosophy from cosmology to epistemology. For Heraclitus, repudiating empiricism, *logos* (reason) is the organizing principle of the cosmos, and fire is either the *archē* or the catalyst effecting change. The principle of Strife maintains equilibrium

Sculpted head of Aristotle, pupil to Plato and tutor to Alexander the Great. New York Public Library.

in sensible matter and enables change in the world. Heraclitus raised a question that would dominate future thinkers. Is change possible? If so, how does change in matter happen? His claim—that wisdom is gained through understanding how *logos* guides the world—characterizes all subsequent philosophy.

Ensuing thinkers developed pluralistic physical systems. Empedocles (fl. 460–430 BCE) suggested a four-element theory (earth, water, air, fire), favored by Aristotle. Change results from the oscillating forces of Love and Strife: when the universe tends to total Love, the elements are completely mixed; when Strife dominates, the elements are completely separated. Democritus (fl. 440–380 BCE) proposed the atomic system, promoted by the Epicureans: the sensible world consists of void (nothingness) and atoms, uncuttable building blocks of nature, potentially infinite in size, shape, and texture. Anaxagoras (fl. 480–430 BCE) posited the radically pluralistic (and stridently rejected) system of seeds, wherein a portion of everything exists in everything, evoking Anaximander's *to apeirōn*.

Although thinkers continued to debate cosmology, focus turned towards ethics and epistemology. The Pythagoreans in southern Italy fostered two distinct schools (fifth century BCE): *mathematicoi* and *acousmaticoi*. The *mathematicoi* (the knowers) advanced a physical system of numerical atomism: all things derive from number, and the properties of number determine the properties of matter, a nascent step towards deductive proof. In contrast, the *acousmaticoi* (the listeners), emphasizing mysticism and authority, were likely influenced by Thracian or Scythian shamanism. The *acousmaticoi* adhered to a communal, ascetic lifestyle, promoting strict ritual purity (especially abstinence from bloodshed), wherein adherents remained free from pollution to enable the soul to rise to its true and god-like state. Xenophanes (c. 520 BCE) was the first Greek to form a concept of a cosmic god (evolving into Plato's Demiurge and Aristotle's Unmoved Mover) and to contemplate the distinction between opinion and knowledge systematically. Satirizing anthropomorphism and polytheism, he wrote, "if cattle or horses or lions had hands and could draw, and could sculpt like men, then the horses would draw their gods like horses, and cattle like cattle; and each they would shape bodies of gods in the likeness, each kind, of their own."

Parmenides (fl. 490–450 BCE), promoting abstraction, categorically denied the value of empiricism. Believing that there exists only *being*, a single, unmovable, unchangeable entity, Parmenides distinguished between reality (The Way of Truth) and appearances (The Way of Seeming). Change is impossible; existence is timeless and static. In contrast, the world of appearances is deceitful, human interpretations of nature are fallacious (as Heraclitus thought), and apparent change in the world is illusory. Significantly, Parmenides, who had studied under Pythagoreans, employed deductive "proofs"—carefully structured arguments leading from "correct" initial assumptions to incontrovertible conclusions—influencing future rational dialogue.

Philosophers responded in various ways to Parmenides's assertions about change. Zeno (c. 490–430 BCE), whom Aristotle called the "Father of Dialectic,"

Jean-Léon Gérôme, *Socrates Seeking Alcibiades in the House of Aspasia* (1861). Oil on canvas.

employed paradoxes to explore Parmenides's claims. In the paradox of Achilles and the tortoise, Zeno suggested that the fleet-footed hero could never overtake the sluggish tortoise since Achilles must first cover half the distance traveled by the tortoise. Since it is impossible for Achilles to traverse an infinite number of points (Zeno assumed that space is infinitely divisible), the tortoise will always remain some distance ahead. Aristotle criticized Zeno's premise as faulty.

Sophists

The sophistic movement of the fifth century BCE represented a new intellectual approach: traveling scholars taught intellectual skills, especially rhetoric and persuasion, for money, hence, as Plato argued, debasing those skills. The Sophist Protagoras (fl. 460–420 BCE), famously claiming that “Man is the Measure of All Things” (quoted without context), promoted an epistemology of relativism—a belief is true provided it appears true to the believer—which Plato refuted.

Plato

In tackling questions of cosmology, ethics, epistemology, and the nature of *phusis*, and in directing attention to rules of reasoning, argumentation, and theory-assessment, Plato (427–348/7 BCE) is the culmination of the Pre-Socratic achievement. Plato studied

under Socrates, who wrote nothing, but firmly shifted philosophy to politics and ethics. Plato is as influential for his thought as for his genre: in his dialogues he never appears as a speaker, but writes as several different characters (Socrates being the most persuasive and influential); the tactic distances Plato from the views of his interlocutors and forces the reader to engage actively with complex and sometimes inconclusive issues instead of passively accepting Plato's authority.

Plato believed that order in the universe was beauty (*ta kalon*, literally “the beautiful”) and that things displaying order are worth studying. Plato also proposed the first systematic teleological account of the cosmos, constructed according to plan by the Demiurge, a benevolent and rational Craftsman who, with the best arrangement in mind, imposes order externally. To answer Parmenides's rejection of change, Plato proposed the Theory of Forms. Incorporeal, insensible, changeless, and knowable, Forms exist eternally and changelessly, in contrast with the changing world of becoming. Objects in the sensible world are merely shadows of idealized Forms, for example, no two tables are ever alike to the smallest detail (knots, warping), and no sensible table will ever replicate the ideal. Sensible tables, nonetheless, partake of the ideal (shape, materials, function). Hence, both change and stability are genuine. The Allegory of the Cave, in *Republic* book 7, illustrates the theory.

The difficulty of ascertaining Plato's authentic ideas (presented ambiguously in the dialogues) gave rise to two major Platonic traditions. His school at Athens, the skeptical Academy, active until the first century BCE, argued against other philosophical views without advancing original views of its own. Later Platonists sought to study and further Plato's ideas systematically.

Aristotle

Plato's most famous student was Aristotle (384–322 BCE), mentor of Alexander the Great (Alexander of Macedon), and a scholar who maintained absolute ascendancy over European science until the seventeenth century. Extant are Aristotle's unpolished lectures delivered at his school in Athens, the Lyceum. Rejecting the mathematization of nature, Aristotle established methods of research and inquiry, favoring empirical observation and deductive argument.

Rejecting Plato's theory of Forms, Aristotle argued that objects could be understood only through knowledge of function and that sensible objects were reducible to four causes: (1) formal—received by a thing (shape); (2) material—the thing underlying a form (for example, marble); (3) efficient—effecting change (for example, a sculptor); (4) final—the purpose served by the change (for example, beautification or patronship). The final cause takes priority over but does not exclude the others: a saw's purpose determines its material (iron) and form (shape). Properties (for example, color, weight, texture) cannot exist independently from their objects, and objects are composites of form (hardness, color) and matter (rock, wool): for example, there are no perfect dogs, just individual dogs, some with droopy ears, others with short tails. Aristotle avoids the Parmenidean problem of change in arguing that change occurs not from non-being to being but from potentiality to actuality: seeds are potential plants, and growth occurs by addition. Change occurs with respect to substance (birth or death), quality (wax softens with

heat), quantity (growth and diminution), place (motion). Change and motion can be traced back to the natures of things: it is the nature of an acorn to become an oak tree.

Hellenistic Philosophy

Under Alexander the Great, a new spirit of internationalism expanded cultural possibilities, especially at centers of learning that attracted students from the entire Greek-speaking world. Philosophical schools flourished in Athens and Alexandria, and writings were formalized into three genres: (1) successions (lineages of teachers and pupils, including major and minor figures); (2) doxographies (systematic accounts of views of different philosophers on certain topics, arranged to demonstrate contradictions or differences between schools); (3) treatises on schools of thought (summaries of a school's main doctrines).

Two schools of thought prevailed: Epicureanism and Stoicism. Both shared the same aims: to secure happiness, and to be free from anxiety and fear. Both taught that irrational fears derive from ignorance of the causes of natural phenomena. Both considered the study of physics and ethics essential in eradicating irrational fears and achieving the *summum bonum* (the highest good), and they agreed that the purpose of philosophy is to obtain peace of mind. The schools disagreed on details of physics and methods of seeking the *summum bonum*.

Epicureanism

Epicurus (fl. 310–270 BCE) reflected the Hellenistic spirit of individualism and self-expression in a culture where there remained few opportunities for political career and government involvement. Epicurus's system of philosophy, ethics, and physics, taught at the "Garden," his school in Athens, was derived from atomism. Augmenting Democritus's atomism, Epicurus asserted that atoms move constantly downward but are occasionally subjected to

A great value of antiquity lies in the fact that its writings are the only ones that modern men still read with exactness. • **Friedrich Nietzsche (1844–1900)**

“swerve,” enabling collisions (resulting in compound objects), hence reconciling conflicts between teleology (fate) and free will. Epicurus believed in a materialistic cosmos strictly guided by the properties and arrangement of atoms, whereby all phenomena could be explained.

Epicureanism has its most eloquent expression in the Latin poet Lucretius (c. 90–55 BCE) whose epic poem *On the Nature of Things* preserves Epicurus’s teachings. Lucretius asserted the materialistic nature of the world. Only atoms and void endure. Atoms and void account for change in the world. Sensible objects (including the human soul) are created from and destroyed back into constituent atoms. Individual atoms can recombine to create any number of sensible objects or living creatures. That atoms exist is provable by observation: wind can be felt; water evaporates; metal and stone erode. All phenomena, including disease and extraordinary natural phenomena (lightning, thunder, earthquakes, rainbows, volcanoes, magnetism), can be explained by the properties of atoms. The greatest good is *ataraxia* (freedom from anxiety), achieved only through study of natural philosophy to counter superstition and fear caused by ignorance. Learning and study cannot eradicate natural inclinations but can rearrange the soul’s atoms so that humans may live in a state of *ataraxia*.

Stoicism

Zeno (c. 334–262 BCE) founded a school in Athens at the *Stoa poikile* (painted porch), which gave the school its name. Stoicism sought to conform private and political existence to an orderly cosmos. Following Aristotelian physics (plenum, mutable and transmutative elements, natural motion), Stoics believed that everything is in contact with a fiery divine soul, and that elements derive from and will return to fire. Change and movement occur through *pneuma* (soul, spirit), binding the cosmos via *tonikē kinēsis* (kinetic tension) which in turn imposes cohesion and equilibrium with simultaneous motion in opposite directions.

The Stoics adapted the ethical system of the Cynics, whose followers interpreted the dictum “live according to Nature” with extreme primitivism. Stoics maintained that emotions are always bad, the only good is virtue, and virtue alone is sufficient for happiness. Virtue includes fulfilling obligations to the state (for example, political life). Consequently this duty-based philosophy flourished among obligation-obsessed Roman intellectuals, including Cicero, Seneca the Younger (c. 4 BCE / 1 CE–65 CE), and the emperor Marcus Aurelius (121–180 CE).

Roman Initiatives

Philosophy largely remained the purview of Greek intellectuals. Until the mid-first century BCE Romans, who expelled philosophers from the city by praetorian edict (in 161 BCE), rejected Greek philosophy as impractical, distracting, and disruptive. Romans eventually found Greek ethics attractive but eschewed speculation and mathematics. Cicero promoted mathematics only for sharpening the wits. Greek philosophy became Romanized with its emphasis on politics, ethics, and duty.

Cicero (106–43 BCE), heavily influenced by the skeptical tendencies of Platonism, made philosophy accessible to a Roman audience. He summarized the major philosophical schools and mined Roman history for examples of appropriate conduct and illustrations of philosophical arguments. Developing a Latin philosophical vocabulary, Cicero invented Latin words (*essentia*, *qualitas*, and *moralis*; essence, quality, and moral in English) to translate Greek concepts. He employed philosophy politically, hoping to defend and revive the Republic through renewed commitment to virtue among the ruling classes, motivated by desire for fame, wealth, and power.

Cicero prominently influenced later philosophers: Augustine (354–430), turned from sin to philosophy and God by Cicero’s (now lost) *Hortensius*; Thomas Hobbes (1588–1649) and Bernard Mandeville (1670–1733), arguing against moral

Cesare Maccari, *Cicero Denounces Catiline* (1882–1888). Fresco. Cicero mined Roman history for examples of appropriate conduct and illustrations of philosophical arguments.

skepticism; David Hume (1711–1776), whose *Dialogues Concerning Natural Religion* was modeled on Cicero's *De natura deorum* (On the Nature of the Gods); and John Locke (1632–1704), whose political philosophy is reflected in the U.S. Declaration of Independence.

Neoplatonism

The final stage in ancient philosophy was with Neoplatonism (a modern term), the dominant philosophical system of the late antique world. It deeply influenced Christianity, Byzantine, and Islamic philosophy, and Renaissance Humanism (with the interest of the fifteenth-century thinkers Giovanni Pico della Mirandola and Marcilio Ficino). Incorporating Aristotelian logic, Stoicism, and mysticism, Plotinus (204–270 CE) aimed simply to elucidate Plato's philosophy and defend Platonism against Peripatetic and Stoic critics. But his interpretations, especially regarding the nature of the soul, evolved into an original scientific philosophy of religion. Investigating the relationship between soul and body, Plotinus posited three underlying, intelligible, and divine substances: the One (identifiable with the Form of the Good of Plato's *Republic* book 6, the ultimate cause of the sensible world); the Intellect; and the Soul, from which everything else transpires. Plotinus identified the human self with the transcendent, intellectual soul (not the embodied soul which enlivens the body). The highest goal of

existence is the soul's return to the One through *henosis* (unity).

His student Porphyry (c. 233–305 CE) published Plotinus's writings and wrote commentaries on them. Porphyry's student Iamblichus (fl. 300–327 CE), incorporating Pythagoreanism, argued that the connected soul pervades the body. Theurgy, hence, is necessary to liberate the soul from the pollution of the body. Later Neoplatonists include Proclus (411–485 CE), who sought to systematize all Greek philosophy, and John Philoponus (490–570 CE), whose commentaries on Aristotle provide continuity between the Greco-Roman, Islamic, and Renaissance traditions.

Despite the emperor Justinian's closure of the Academy in 529 CE, Greek and Roman philosophy endures, as thinkers continue to address questions raised by Greco-Roman philosophers and engage with their answers.

Philosophy, Modern

Beginning with René Descartes (1596–1650), modern philosophers in the West began to reexamine ancient questions about whether the foundation of knowledge is in the mind or the senses—that is, in reason or experience—sometimes by drawing on scientific, mathematical, and analytic approaches. Despite radically differing opinions, these modern thinkers gave primacy to the rational mind, and especially consciousness, as the starting point for philosophical reflection.

Philosophy is a form of rational inquiry into the nature of reality. Though there is no decisive date that marks the beginning of modern philosophy, René Descartes (1596–1650) is generally considered the first modern philosopher. The fact that philosophers often work on problems raised by much earlier philosophers, however, makes it hard to divide sharply between periods. Because modern philosophers disagree radically on the nature of philosophy, it is also difficult to define what is unique about modern philosophy. Nevertheless, in contrast with ancient and medieval philosophy, one distinguishing feature of modern philosophy is the primacy it gives to the human mind, and especially consciousness, as the starting point for philosophical reflection. Though by no means uncontested, this concern for the subjective primacy of rational inquiry played an important role in helping to articulate the distinctively Western experience of modernity.

From Descartes to Kant

René Descartes was a veteran of the seventeenth-century wars of religion that ravaged Europe, and

his desire to find a secular foundation for knowledge that would escape entanglement in religious disputes had an enduring influence on the shape of modern philosophy. Striving to imitate the precision of mathematics, Descartes proposed to show how the human mind can reliably know things by describing cognition from within. This involved carefully distinguishing between what the mind could know as “clear and distinct,” and the potentially deceptive impressions of the senses. Though himself not a skeptic, Descartes has been accused of encouraging skepticism by thus radically separating mind and body. His own solution to this “Cartesian dualism” was to insist on the reality and benevolence of God as guarantor of clear and distinct knowledge.

Following Descartes, philosophy came to be divided into what historians of philosophy call rationalism and empiricism. Rationalists follow Descartes’s insistence on the unreliability of sense perception, and respond by treating the components of thought (intuitions, ideas, etc.) as primary data for understanding the true nature of reality. They also follow Descartes by holding that the connections between physical and spiritual reality lie, ultimately, in the essence of God, who is characterized less as a personal deity than a logical necessity to explain reality. Leading rationalists include Baruch Spinoza (1632–1677) and Gottfried Wilhelm Leibniz (1646–1716). Empiricists, on the other hand, reject the notion that the mind knows only itself. They stress the immediate encounter with sensory impressions as the proper starting point for philosophical reflection, and warn against the potential of unchecked speculation to muddy the otherwise clear presentation of reality in the senses. Though often seen as an antidote to the skepticism resulting

Pages from *Principia philosophiae* by René Descartes (1596–1650).

Beinecke Rare Books and Manuscript Library, Yale University.

from rationalism, extreme empiricism can also undermine certainty about knowledge. David Hume (1711–1776), for instance, observed that there was nothing in the sensory perception of causal events, like one billiard ball striking and moving another, which explained how the mind perceived such events as necessary.

The Königsberg philosopher Immanuel Kant (1724–1804) proposed to resolve the dilemma Hume raised by establishing the limits of reason, and understanding how within those limits, the mind was able to have certain knowledge. In his *Critique of Pure Reason* (1781), Kant argued that the necessity one experienced when perceiving causality was an effect of the way the mind organized the experience. It was, properly speaking, “synthetic *a priori*” knowledge: synthetic, because it required experience of the event, *a priori*, because the necessity supplied in and by cognition was itself logically prior to any experience. Any attempt to thus radically prioritize either reason or experience in the manner of extreme rationalism or empiricism, was thus doomed to failure. Instead, according to Kant, philosophy must begin with a wholesale “critique” of the conditions for the possibility of any knowledge. This drive to make philosophy both systematic and critical played a major role in shaping the great philosophical systems of the nineteenth century. It was also, in part, what motivated dissenting voices to join in the broadly artistic, but also philosophical, movement known as Romanticism. Drawing on the philosophy of Jean-

Jacques Rousseau (1712–1778), who stressed society’s corrupting influence on the natural goodness of individuals, Romanticism sought to rehabilitate the importance of the natural and nonrational dimensions of human life.

Kant’s critical philosophy was a major achievement, but did not satisfactorily bridge the gap left by Cartesian dualism. Indeed, Kant himself seemed, to many, to have reinforced the problem by steadfastly denying that the phenomena of perception could tell us anything about “things in themselves.” Kant’s critical philosophy thus led to a truncated conception of experience in which, as with the rationalism he claimed to overcome, the mind only really knew itself. What distinguished Kant from Descartes, however, was Kant’s analysis of a “transcendental” realm of categories that, while not part of the empirical world, were also not reducible to human psychology. This transcendental realm was especially important for the evolution of absolute idealism in the nineteenth century.

Great Systems of the Nineteenth Century

Associated with figures like Johann Gottlieb Fichte (1762–1814) and the early work of Friedrich Schelling (1775–1854), absolute idealism went beyond the notion that reality was only knowable through the mind to the proposition that reality was fundamentally identifiable with mind. For Fichte, and subsequently

for Georg Wilhelm Friedrich Hegel (1770–1831), looking for the nature of reality by supposing the activity of the material world on human perception was a dogma that Kant had inherited from the empiricists. The transcendental deduction of categories showed, on the contrary, that reality itself was fundamentally immaterial, or “spiritual.” The task for philosophy therefore was not to understand how thought conformed to the physical world, but to understand how spirit manifested itself as reality. Hegel solved this question by analyzing the course of world history, claiming to show how the unfolding of concrete concepts and forms of thought was nothing but a dialectic through which spirit came to know itself by negating and superseding previous thoughts. According to Hegel, the goal of history to realize World Spirit in self-consciousness expressed as freedom; he devoted his philosophical career to elaborating a comprehensive system devoted to showing this progression in all aspects of world history.

Though discredited in the eyes of philosophers today, Hegel’s attempt to explain systematically the course of world history inspired a generation of philosophical followers. The most famous of these so-called young Hegelians was the philosopher and political economist, Karl Marx (1818–1883). Marx advanced an inversion of Hegelian philosophy that he called “dialectical materialism.” Where Hegel saw the movement of history in terms of a dialectical movement of spirit, Marx held that the dialectic of material conditions was the primary mover of history. This dialectic manifested itself in concrete terms in the class struggle, but was equally at work in forms of thought, like religion and philosophy, that Marx exposed as ideology. Though this led Marx to abandon philosophy in favor of political economy and history, his early philosophical work manifests a deep concern for the underpinnings of human freedom that is revived in the twentieth century as a kind of Marxist humanism. This turn from philosophy to political economy finds an important parallel in the “positivism” of Auguste Comte (1798–1857). Like Hegel, Comte sought to understand systematically the unfolding of world history, but argued that rigorous

Julius L. Sebbers, *Georg Wilhelm Friedrich Hegel* (c. 1828). Hegel sought to understand how spirit manifested itself as reality, not how thought conformed to the physical world.

empirical science and not philosophy was the pinnacle of human knowledge.

Phenomenology

By the end of the nineteenth century, modern philosophy felt decisively overshadowed by the rise of the natural and social sciences alike. The catastrophic destruction of World War I also prompted many to question some of the more pretentious claims of philosophy, and Western civilization as a whole. In this context, Edmund Husserl (1859–1938) sought to rejuvenate philosophy by putting it on a scientific footing. For Husserl, one needed to distinguish precisely between the contents of consciousness and the means by which consciousness grasped these specific contents. By thus “bracketing” the contents of consciousness, one could then isolate the “eidetic essences” by means of which consciousness comprehended the great variety of particulars in experience. Such essences were

Work while you work, play while you play—this is a basic rule of repressive self-discipline. • **Theodor Adorno (1903–1969)**

not, as in Plato, meant to imply the existence of real universals, but served instead as working postulates for discriminating necessary from accidental features of acts of consciousness. Though criticized by some as “psychologism,” apprehending the acts of consciousness with an almost empirical rigor convinced Husserl that he had established the subjective basis for pure logic. Phenomenology exerted a strong appeal both inside and outside of philosophy, and has been influential in areas such as sociology and hermeneutics. One important legacy of phenomenology is the concept of *lifeworld*, which draws attention to the links between science and other formalized modes of thought and the conditions of everyday life.

Existentialism

One of the most influential students of phenomenology was Martin Heidegger (1889–1976). Though his philosophical work is often considered suspect because of his support of the Nazi movement in Germany, Heidegger achieved a substantial reorientation in philosophy by recalling the original Greek concern for the question of being. This original metaphysics cannot and should not be subjected to scientific inquiry, because it precedes it as the basic question about human existence as such. Indeed, for Heidegger, humanity is defined precisely as the being for whom being is a matter of concern, and this led him to stress the decisive importance of death as the end toward which being knows itself to be moving. Based on his refusal to subject the question of being to analysis by mundane scientific tools, the later Heidegger defended the thesis that language and even poetry were better suited to what he called the “task of thinking.” He developed increasingly complex modes of expression as a result, and this linguistic esotericism has influenced the evolution of postmodern philosophy.

Though Heidegger is usually taken to have inaugurated the “existential” turn in philosophy, one should not overlook the strongly existential dimension of earlier thinkers such as Søren Kierkegaard (1813–1855) and Friedrich Nietzsche (1844–1900). A critic of Hegel, Kierkegaard held that key personal decisions in

life, such as love and faith, could never be subsumed philosophically in a system. Throughout his many writings, he drew attention to irresolvable contradictions as a means of heightening consciousness of oneself as the arbiter of existence. Similarly, Nietzsche sought to expose the lifeless herd-mentality of modern existence by means of a relentless critique of middle-class norms. To realize its full potential, humanity had to embrace its fundamentally creative mission, and this meant reversing, or “transvaluing,” values in order to accept the fact that destruction was a necessary part of creation. Although Nietzsche’s writing betrays a distinct pessimism, reflected in his depiction of the “super-man” as the only one able to break through conformity, the will to power represents a philosophical claim about the nature of culture as ideology, not a celebration of egoism at all costs.

Analytic Philosophy

Rooted in earlier traditions of empiricism, analytic philosophy emerged in the twentieth century to become the dominant form of professional philosophy. Sometimes misnamed as “Anglo-American” philosophy, analytic philosophy has important roots in the Vienna Circle and in a number of other German-language thinkers, such as *c* (1848–1925) and Franz Brentano (1838–1917). Its various manifestations also make it impossible to speak of anything more than a shared spirit of philosophical inquiry. The basic orientation of analytic philosophy is the conviction that philosophy is restricted to analyzing the basic truth or falsity of propositions about states of affairs. For analytic philosophers, the mistake of much previous philosophy was to confuse such propositions with the poetic or emotive uses of language. Bertrand Russell (1872–1970), a logician and mathematician, strongly influenced the development of analytic philosophy with his view that reality could be explained according to the atomic structures of perception and the logical inferences binding them together into wholes. Ludwig Wittgenstein (1889–1951) reinforced logical atomism in his earlier work, but shifted in his later philosophy to a repudiation of the view that language

was reducible to propositions. This paralleled some of what Heidegger was saying, and opened analytic philosophy to a better appreciation of the importance of ordinary life as the mainspring of language use.

The search for a rational kernel that might guide human affairs has been at the core of modern philosophy, since at least Descartes. But the presumption that this kernel rests in consciousness has been subject to challenge on a variety of fronts, including: the growing interest in the neural and biological bases for thought, and the unmasking of philosophy as a tool underwriting social order. While not undermining the basis of philosophy as such, these new perspectives have done much to expose the history of philosophy's distinctly Western presuppositions and prejudices.

Pilgrimage

The word *pilgrimage* is derived from the Latin words *per* (meaning “through”) and *ager* (meaning “field” or “land”). People usually think of pilgrimage as involving a journey—made either alone or in a group—to and from a sacred site. Pilgrims often perform rituals not only at the sacred site itself, but also at the beginning and end of the journey. In addition, pilgrims may visit other holy places during the course of the journey.

Since ancient times people have been engaged in pilgrimage, either alone or in groups, leaving their homes to journey to a sacred place. Motivations for pilgrimage can include a desire for divine healing, penance for a wrong committed, thanks for a prayer answered, fulfillment of a religious injunction, or some combination of these motivations. The fact that pilgrimage occurs, in some form, in so many societies makes studying this phenomenon fascinating but difficult.

Pilgrimage in the Classical World

No single word in Greek or Latin specifically described travel to a holy destination, but festivals brought together people from scattered settlements both to celebrate the gods and to engage in trade. The numerous shrines of the Hellenic (Greek) world illustrated a great variety of possible reasons to travel. The frieze (an architectural ornament in the form of sculptured, horizontal band) of the famous Parthenon in Athens commemorates the Great Panathenaea, an event celebrated every four years and aimed at achieving a union of all Athenians. Epidauros provided a

place for the god Apollo and his son Asklepios to cure the sick. Delphi delivered prophecies through the medium of a priestess. At Olympia the festival of Zeus was celebrated with sporting competitions every four years—an event echoed in the contemporary games, which have taken on global significance in their revived form. Wealthier people in particular had the resources to travel, and pilgrimage also provided one of the few opportunities for women to travel outside their home cities. Roman patterns of pilgrimage were often modeled on Hellenic precedents, with numerous gods celebrated in shrines of greater or lesser size, but with few written doctrines or rules being drawn upon.

Pilgrimage in the World Religions

Pilgrimage is performed in all of the great religions and is usually—unlike its position in the classical world—provided with a justification and model in sacred texts. The degree to which pilgrimage is seen as obligatory varies. Islam is the most prescriptive faith. Every Muslim is required to perform the hajj (pilgrimage to the holy city of Mecca in Saudi Arabia) at least once unless prevented by illness or lack of economic resources. The binding nature of the hajj is combined with other features that distinguish it from other activities. Only Muslims are allowed to enter the holy city; the timing of the pilgrimage is fixed at certain days within the twelfth month of the Muslim year; and pilgrims, dressed in two sheets of unsown cloth or plain dresses, must perform a predetermined sequence of ritual actions, including walking seven times around the Kaaba, the cube-shaped stone building in the court of the Great Mosque.

Hindu pilgrims enter the Shri Ranganath Temple in Vrindavan, India. Photo by Klaus Klostermaier.

Just as the practices of the hajj developed out of earlier traditions already extant in the Arabian Peninsula of the seventh century CE, so Islam emerged within a wider sacred landscape already occupied by Judeo-Christian religious assumptions and influences. The Prophet Muhammad (c. 570–c. 632 CE) regarded Jerusalem as sacred, and the seventh-century Dome of the Rock—even today an object of Muslim pilgrimage—was constructed on the site of the former Jewish Temple and resting place of the Ark of the Covenant in Jerusalem. The hajj had some parallels with the *haggim* of Judaism, the ancient pilgrimage feasts involving the convergence of the Israelites on Jerusalem. (The Hebrew term *hag* implies the actions of turning around and dancing.) But such feasts also expressed specific aspects of Jewish history. The oldest feast, Passover, celebrated deliverance from servitude in Egypt. Tabernacles involved the construction of temporary shelters and commemorated the forty years spent by the Jews in the wilderness. Shavuot (Weeks) was a harvest festival that also marked the giving of the Ten Commandments to Moses on Mount Sinai. These gatherings therefore provided occasions for pilgrimage while also recalling different forms of movement: escape from slavery, wandering in the desert before locating the Promised Land, or ascending a mountain. They are still celebrated by members of a faith whose identity remains rooted in the experience

of dispersal, the so-called Diaspora (the settling of scattered colonies of Jews outside Palestine after the Babylonian exile). Even today, two thousand years after the final destruction of the Temple but with the State of Israel restored, Passover is an occasion when many Jews proclaim: “Next year in Jerusalem!”

Christianity echoes Islam and Judaism in its reverence for Jerusalem, both in relation to scripture and in relation to pilgrimage. The landscape of the Holy Land and the holy city have provided potent reminders of Jesus’ life as well as of the location of his future return (just as in Islam Paradise will be transferred to Jerusalem during the Last Days). The early centuries of the church brought the quick emergence of a pious tradition of traveling. During the fourth century CE Helena (c. 255–327 CE), the mother of the Roman emperor Constantine (c. 274–337 CE), toured the Holy Land, adapting the model of traditional Roman imperial progress through a province for her own spiritual as well as political purposes. As the Christian empire developed so did the pilgrimage routes of often highly ascetic travelers, who expected to see the biblical narrative played out in the places visited. A growing monastic tradition was also evident in Palestine and neighboring lands. But with the decline in Muslim tolerance of Christian visitors to Jerusalem from the tenth century onward, European sites became increasingly prominent pilgrimage locations. Rome housed the tombs of St. Peter and St. Paul, and other shrines, such as Santiago de Compostela in northwest Spain, were viewed as symbols of Christian military opposition to Islam, celebrating St. James in his role as a warrior, armed with both a sword and a cross. Some sites even replicated the sacred landscape of the Holy Land, such as Walsingham in Norfolk—known as “England’s Nazareth” because it claimed to have an exact copy of the holy house that Jesus had inhabited as a boy.

The qualities of the landscape have been central to Judeo-Christian pilgrimage traditions, but also—and perhaps especially—to those of south Asia. The Hindu term *tirtha-yatra* means broadly “journey to river fords,” illustrating a devotion to flowing water evident since Vedic (relating to the Hindu sacred

The 1908 travel route of pilgrim Charles Mason Remey, a teacher and defender of the Baha'i Faith.

writings) times (from c. 1500 BCE), and pilgrimage practices often involve taking a purifying dip, as well as visiting holy figures or gaining sight of a deity contained within an image. The *Mahabharata* (c. 300 BCE), a Vedic epic, contains sections describing and noting the religious merit to be gained from visiting numerous *tirthas* (sacred places). Such merit is said to apply to people of all classes and castes and usually involves a temporary renunciation—akin in some ways to Christian asceticism—that rejects bodily comforts and pleasure. As one scholar of Hindu pilgrimage puts it, “The returning pilgrim should be thinner and poorer” (Gold 1988, 263). Other important features of the Hindu pilgrimage landscape include hilltops, caves, and forests, creating a complex sacred geography that encompasses the whole of India. Furthermore, with the economic migration of Hindu populations into the West, features of the sacred Indian landscape have been translated into new parts of the world, so that, for instance, the convergence of two rivers in Ohio has been compared by some Hindus with the confluence of the sacred Indian rivers: the Ganges, Yamuna, and Sarasvati.

On the Indian subcontinent the religions of Jainism and Sikhism maintain pilgrimage traditions that have some similarities with Hindu practices. According to Buddhist tradition, among the last words of Buddha (c. 563–c. 483 BCE) were instructions to his followers to visit places marking the most significant events

of his life. People soon added numerous holy spots to this biographical landscape, within and beyond India. Just as the emperor Constantine reinforced his imperial power by placing pilgrimage churches in the Holy Land, so the emperor Ashoka—the first Buddhist pilgrim of whom we know—used imperial patronage during the third century BCE to create a Buddhist landscape of pilgrimage by improving roads and resting places for travelers. As the religion itself spread, new pilgrimage sites emerged in China, Tibet, and Japan.

Similarities and Differences

Both in the past and in the present pilgrimage practices across the world's religions have appeared to exhibit some striking similarities. Circumambulation of shrines and other sacred objects is evident not only in Islam but also in Hinduism and Buddhism, for instance. Pilgrims also commonly take some material evidence of their journey back home—perhaps a vial of holy water, an image, or a token. However, we should not assume that actions that look similar from the outside have the same meaning to participants from different cultures and religions. Furthermore, pilgrimages have tended to contain within them—even to foster—conflicts between pilgrims supposedly united by the same religion or between ordinary pilgrims and shrine authorities. Thus, the famous Catholic site of Lourdes, situated on one

Life is a pilgrimage. The wise man does not rest by the roadside inns. He marches direct to the illimitable domain of eternal bliss, his ultimate destination. • **Swami Sivananda (1887–1963)**

of the main medieval pilgrimage roads of southern France and commemorating the visions of the Virgin Mary granted to a young girl during the nineteenth century, is enormously popular in the present, attracting millions of visitors a year. Such popularity inevitably creates tensions over the varied motivations of the pious, for instance, between the desire for miraculous healing expressed by the sick who visit the site and the general emphasis on spiritual rather than physical benefits that is promoted by the clergy.

The religious and often political (and even economic) power contained in many pilgrimage sites has often led to acute, even destructive, conflicts. Jerusalem is not the only site of competition between faiths. The pilgrimage center of Ayodhya in Uttar Pradesh, India, remains a site of troubled relations between Hindus and Muslims, resulting not only in violence but also in rivalrous construction and destruction of sacred buildings. Elsewhere in India, the Golden Temple at Amritsar, holiest of shrines for Sikhs, became the center of conflict between religious separatists and the Indian government, leading in 1984 to the storming of the temple by the army and the killing of many people, including pilgrims.

Pilgrimages have also been attacked from within their religious traditions, with critics often denying the value of physical travel or challenging the idea that the divine can be particularly located in a single spot on Earth. The tenth-century Sufi (Muslim mystic) authority Abu Sa'id enjoined his followers not to undertake the hajj on the grounds that they should concentrate on cultivating mystical experiences instead. Within Hinduism some writers have argued that pilgrimage implies too much attachment to the material world. A key aspect of the Protestant Reformation was the iconoclasm that denied the spiritual value of the statues and relics in numerous shrines and that attacked the economic corruption in both the guardianship of sacred sites and the selling of "indulgences"—remissions of punishments for sin that the Catholic Church granted in return for pious acts such as pilgrimage.

Pilgrimage in the Future

Despite some predictions that the world is becoming more secular, pilgrimage remains a flourishing institution. Although it has always been combined with other activities, pilgrimage is increasingly being associated with tourism, so that sacred travel is often undertaken alongside other forms of leisure, and pilgrimage sites have become accustomed to hosting both pilgrims and tourists at the same time. As more people can more easily travel throughout their own countries or even across the globe, pilgrimage seems likely to become an ever more visible part of life in the twenty-first century.

Piracy

Piracy on the high seas—the theft of a ship’s cargo, the ship itself, and the violence or kidnapping it involves—has existed since ancient times. In the twenty-first century piracy poses an ever-greater threat, costing commercial shipping enterprises billions, disrupting international trade, and endangering lives.

According to the 1982 United Nations Convention on the Law of the Sea (UNCLOS), piracy is any illegal act “of violence or detention . . . committed for private ends by the crew or the passengers of a private ship or a private aircraft, and directed . . . on the high seas, against another ship or aircraft, or against persons or property on board such ship or aircraft.” This definition is the product of high-level deliberations in an age of nation-states, but it captures the essence of piratical activity throughout history. Because of their mobility, their tendency to operate in places frequented by commercial shipping, and the fact that the theft of a ship’s cargo—and often of the ship itself—disrupts international trade, piracy often has far-reaching implications.

The tendency to romanticize pirates as a class of seagoing Robin Hoods tends to obscure the violent and criminal nature of their actions. Certainly no victim of modern piracy speaks fondly of his or her assailants. It is true, however, that pirates generally create and operate within hierarchies that are relatively flat when compared with those of commercial shippers, privateers, and navies. In the eighteenth century, for instance, the distribution of prize money, for instance, was more equitable than it was among privateers or naval sailors, where the share system favored officers, shareholders or the

government. Likewise, there have always been divergent views of piratical behavior. In the first century BCE, Cicero held that a pirate “is not specified as belonging to the ranks of combatants, but is a foe in all men’s eyes,” (Walsh 2001, 121) a sentiment echoed by the seventeenth-century English jurist Sir Edward Coke, who called pirates the enemy of mankind. A contrary perspective is found in St. Augustine’s *City of God*, which relates a conversation between Alexander the Great (Alexander of Macedon, 356–323 BCE) and a pirate who asks: “How darest thou molest the whole world? But because I do with a little ship only, I am called a thief: thou doing it with a great navy, are called an emperor” (Pennell 2001, 25). Modern practice follows Cicero and Coke, and “enemy of humankind” (*hostis humani generis*) is used today not only to describe pirates but also in reference to people engaged in terrorism, torture, and genocide.

The conditions in which piracy flourishes make the concept of legality difficult to pin down. One classification of maritime predation distinguishes between parasitic, intrinsic, and episodic forms. Of these, only parasitic qualifies as pure piracy conducted without any legal constraints, such as was found in the Caribbean and western Atlantic during the classic age of piracy, from about 1650 to 1725. This was the era of flags emblazoned with a skull and crossed bones, one of many symbols—albeit a popular one—intended to strike fear in the minds of prospective victims. Government efforts to suppress piracy were every bit as ruthless as the pirates themselves. In 1701 Captain William Kidd, a privateer-turned-pirate wanted for crimes committed in the Indian Ocean, was captured in Boston, hanged at

Blackbeard and his pirates celebrated in Charleston, South Carolina, when they blockaded the port and ransomed its inhabitants in 1718.

London's Execution Dock, and displayed at Tilbury Point on the River Thames as a warning to others. Kidd was only one of many early-eighteenth-century pirates who were tried by government authorities anxious to encourage peaceful trade. The ruthless Edward Teach, or Blackbeard, was hunted down and killed in North Carolina in 1718. In Jamaica two years later, Calico Jack Rackam and his consorts Mary Read and Ann Bonny were captured, tried, and sentenced to death. Rackam hanged, but Read and Bonny, both pregnant, were spared; Read died in prison, Bonny's fate is unknown. The tough measures worked, and within a few years piracy was all but eradicated in the western Atlantic.

An early form of episodic piracy is found in the second century BCE, when Cilician pirates from Asia Minor evolved from relatively small groups into a full-fledged navy that fought against Rome in the Mithridatic Wars. Determined to crush the Cilicians, the people endowed Pompey the Great with

the administrative power of the *imperium* for an unprecedented period of three years in 67 BCE. His campaign was swift and decisive, but the lingering effects of his *imperium* are regarded as a milestone in the metamorphosis of Rome from a republic to an empire.

In the fifteenth century, China's Ming dynasty banned overseas trade, putting tens of thousands of seamen out of work. While the state was unable to suppress smuggling at sea, imperial authorities attempted to check the pirates on land. In the ensuing round of reprisals violence became endemic. Many of the pirates—perhaps forty thousand in all—operated out of bases in Japan. This period of piracy ended when the ban on trade was relaxed and other economic reforms were instituted in the 1560s.

Privateering and corsairing are forms of intrinsic or institutionalized piracy. In the early modern period, European navies routinely commissioned merchant

Captain Richard Phillips, right, in April 2009, was rescued after being held captive by pirates off the coast of Somalia. United States Navy.

ships to sail as privateers against enemy commerce. These were issued letters of marque that outlined the scope of their operations and afforded captured privateers legal protection. The degree to which these niceties were observed depended on the strength of the legal authority. During the American Revolution, privateering in the Gulf of Maine degenerated into indiscriminate violence by “privateers” who owed allegiance to neither crown nor colonies.

Corsairing is another example of state-sanctioned “piracy,” as American Federalists called it. The North Africa regencies of Algiers, Tunis, and Tripoli raised money by capturing merchant ships and ransoming their crews, passengers, and cargoes. Many governments found it expedient to pay the regencies for safe conduct passes, but this practice ended in 1816 when European powers decided to take advantage of their overwhelming superiority and the state of peace prevailing at the time to put an end to it. Privateering was formally outlawed by the 1856 Declaration of Paris.

Piracy has by no means been eradicated, and since 2001 there has been growing concern over the potential collaboration of pirates, whose motives are essentially economic, and terrorists with political aims. The trend toward privatizing certain military and security undertakings also suggests that a return

to some form of private naval warfare is a distinct possibility.

Piracy of commercial transport vessels in the waters between the Red Sea and the Indian Ocean, and especially off the coast of Somalia, continue to cost upwards of \$15 billion a year and threaten lives. In April 2009, during a week-long spate of attacks along the Somali coast, Somali pirates captured the MV *Maersk Alabama*, a U.S.-flagged, 17,000-ton cargo ship on its way to Kenya with relief supplies. When the crew managed to take back the ship the pirates kidnapped the captain, Richard Phillips, to a lifeboat. After four days, believing that Phillips’s life was in danger, U.S. Navy SEAL snipers shot and killed the captors; Phillips was rescued and determined to be in good condition.

Plastics

The 1907 invention of Bakelite, the first fully synthetic plastic, ushered in an era of experimentation in plastics manufacturing. By the 1930s molded plastic goods such as clocks and crockery were the rage, but in the 1960s a proliferation of cheaply made items gave plastics a bad name. Despite the public preference for goods made from natural materials, the plastics industry proves to be remarkably resilient in the twenty-first century.

Plastics are everywhere, yet the term *plastics* is not well defined. The adjective *plastic* means pliable (from the Ancient Greek *plassein*, to mold), yet many plastics (notably Bakelite) are rigid. As a group, the metals are more “plastic” than plastics. Natural materials such as wax or horn are pliable but are not thought of as plastics. Rubber is usually considered separately from plastics (as in this encyclopedia) but hard rubber (ebonite) is a plastic. Any attempt at a technical definition usually ends up including adhesives and synthetic fibers, but excluding an important group of plastics such as the silicones. Our use of the term *plastic* usually depends on the object. The rubber duck is actually made from plastic (PVC, or polyvinyl chloride), yet carbon-fiber tennis rackets are usually not regarded as plastic. We all know what plastics are, but it is a culturally determined term, not a technical one.

The Origin of Plastics

For many centuries, objects have been shaped out of natural materials that could be considered similar to modern plastics, including clay (pottery),

glass, and wood (which has a similar structure to synthetic reinforced composites). Wax, horn, and shellac (made from the lac insect) were even closer to our current concept of plastics. Horn is perhaps the closest of these materials to modern plastics. By the eighteenth century, horn was being molded, using pressure and heat, to produce a variety of objects, especially beakers, medallions, snuffboxes and jewelry. Restricting the use of the term *plastics* to synthetic (or at least semisynthetic) materials, the history of modern plastics began with the accidental discovery of nitrocellulose (cellulose dinitrate) by the Swiss chemist Christian Schöbein in 1845. The British chemist and inventor Alexander Parkes experimented with nitrocellulose in the 1850s, and by 1860 he had made molded objects from this material, which he exhibited at the International Exhibition in London two years later. He patented the idea of adding camphor to soften the stiff nitrocellulose in 1864. Variants of the resulting substance, called Parkesine, were developed in London in the 1870s as xylonite by Parkes’s former works manager Daniel Spill and an American, Levi Merriam, and in Newark, New Jersey, as the better-known celluloid by two brothers, John Wesley and Isaiah Smith Hyatt. By the 1890s, celluloid had become an important material, used to make billiard balls (and other items formerly made from ivory), combs, washable collars and shirtfronts, photographic film, and Ping-Pong balls (invented in 1901 and one of few remaining uses of celluloid). In 1892, two British chemists, Charles Cross and Edward John Bevan, introduced a new cellulose-based material, viscose rayon, which could be molded into combs, handles, and ashtrays, but which became

Plastic in a hydraulic press. New York Public Library.

more important as the first commercially successful semisynthetic fiber.

Bakelite and Style

Celluloid had its uses, but it was expensive, difficult to work with, and flammable (it is related chemically to gun cotton). The real breakthrough for plastics had to await the development of the first fully synthetic plastic, Bakelite. The Belgian-American chemist and inventor Leo Baekeland invented Bakelite in 1907 while trying to make a synthetic lacquer from the reaction between two organic chemicals, phenol and formaldehyde. He used a two-stage process: the chemicals reacted to form an intermediate which was then heated in a pressurized mold to make the final product. Bakelite appeared at the right moment,

when the rapidly growing electrical industry was looking for a good robust material for switches and other components that did not conduct electricity. Although it could be used for domestic goods (billiard balls were an early example), its dark color and lack of translucency was a major drawback. These problems were overcome by the amino plastics (made by the reaction between formaldehyde and urea or melamine), which were colorless and translucent. They could be colored to produce very attractive molded household objects including clocks, ashtrays, and crockery. The first amino plastics were developed by the British Cyanide Company (later renamed British Industrial Plastics) in 1924, and the American Cyanamid Company introduced the melamine plastics in 1939. By the 1930s, plastics manufacturers were encouraging industrial designers, such as Norman Bel Geddes, to create new styles which showed off their products to the best advantage. In this period Bakelite and melamine plastics were particularly associated with Art Deco and the new technology of radio sets.

Wartime Expansion

In the 1930s other plastics were being developed which were very different from Bakelite, being both light and easily shaped. They had existed as laboratory curiosities for almost a century (polystyrene had been discovered in 1839), but they had not hitherto been a commercial success. Polyvinyl chloride (PVC), for instance, decomposed on the hot rollers used to turn it into sheets. By the mid-1930s, however, the American corporation Union Carbide and the German firm I.G. Farben had independently succeeded in producing types of PVC which could be turned into flooring, cable covering, and household goods. The German firm of Rohm & Haas was successfully developing polymethyl methacrylate (PMMA, better known as Perspex or Plexiglas) in collaboration with its American counterpart. In 1933 the British chemical firm ICI (Imperial Chemical Industries) had, by chance, discovered polyethylene (Polythene), which showed promise as a light insulator. The industry was initially

Mural depicting Bakelite Plastic headquarters. In the 1930s Bakelite and melamine lent themselves to Art Deco design and the new technology of radio sets. New York Public Library.

held back by the lack of any serious demand for these new materials, but the situation was transformed by World War II. PVC was used as a substitute for rubber and other materials, PMMA was used to make aircraft cockpits, and polyethylene was used in radar sets. Polyurethanes (used in foams, shoe soles, and stretch fabrics) were a German innovation which was developed in the United States in the 1950s.

Plastics Become Common

After the war ended, the plastics industry needed to find new outlets for its products. Polyethylene was converted into washing-up bowls (dishpans), squeeze bottles, and Tupperware dishes. PVC displaced fragile shellac in long-playing records. PMMA was used to make jukeboxes. Plastics were also used extensively in house building, and in toys, for instance, hula hoops and Barbie (who was “born” in 1959). Hula hoops were among the first examples of a new plastic called high-density polyethylene which first appeared in the mid-1950s. This strategy succeeded beyond the industry’s expectations. While the period between 1945 and 1973 was a highly successful one for the plastics industry in terms of technology, production, and profits, the popular image of plastics eventually took a tumble. Whereas Bakelite had been considered high tech and stylish in the 1930s (except by snobs who always insisted that natural products were better), plastics were regarded as cheap and tacky by the mid-1960s. This was a result of poor manufacturing techniques by some of the mom-and-pop operations that had entered the industry, as well as the use of plastics to make cheap items such as fairground gewgaws and novelties for cereal boxes and Cracker Jacks.

Plastics Become Sophisticated

Despite their popular image, plastics were growing in technical sophistication in the 1950s and 1960s. Glass-fiber-reinforced composites enabled the production of light but very strong casings, which are now widely used in the aerospace and transport industries. Teflon had been discovered by accident in 1938, but Du Pont was opposed to its use in cooking utensils, and the first nonstick pans, made without the firm’s approval, did not appear until 1960. In the 1960s there was a growing demand for heat-resistant plastics, partly because of the space program (and the growing popularity of ready meals) and partly because of the withdrawal of asbestos on health grounds.

The plastics industry also devoted considerable effort to developing substitutes for glass, a potentially enormous market. The polycarbonates, a virtually unbreakable, vandal-proof material used for street lighting, public shelters, and safety visors was developed independently by General Electric and the German firm Bayer in the late 1950s. At the other end of the hardness spectrum, soft contact lenses were first made by a Czech chemist, Otto Wichterle, using a chemical relative of PMMA, in 1961. Attempts to make drink containers from plastics were initially unsuccessful, but a Du Pont team headed by Nat Wyeth (a member of the famous family of artists) was able to blow drinks bottles from polyester resin (better known as a synthetic fabric) for Pepsi in 1975.

Crunch Time for Plastics

The plastics industry, which used petroleum as its raw material, was badly affected by the oil crisis of 1973, when the price of oil quadrupled. Not only

I just want to say one word to you—just one word—“plastics.”

• Walter Brook (Mr. McQuire) to Dustin Hoffman (Benjamin Braddock) in *The Graduate* (1967)

did its costs escalate, the demand for its products fell as Western economies faltered. The public image of plastics was already lackluster. The environmental movement, gaining momentum from the anti-Vietnam War protests, was highlighting the highly visible results of discarded plastics waste. Even more alarmingly, there were growing concerns about the safety of the workhorse plastic PVC. In 1972, the monomer (building block) of PVC was discovered to cause a rare form of liver cancer. More recently there have been concerns about the health effects of plasticizers, chemicals used to make PVC flexible. The producers of traditional materials such as wood, metals, and glass were not idle and capitalized on this public disillusionment. Sometimes the users of these materials, for instance furniture manufacturers, made their products more competitive by incorporating plastics into their products where they would be invisible.

The Resilience of Plastic

Nevertheless, the plastics industry proved to be remarkably resilient. By 1992, American production had trebled over two decades. Meanwhile, the use of plastics continues to grow, in window frames, computers, and in our cars. The high-performance plastics of the 1960s are becoming commonplace, and even more sophisticated plastics are being developed. Carbon-fiber-reinforced composites are used in sports equipment. While the public at large

remains attached to natural materials, we use an ever-increasing amount of plastics (even if we tend not to think of them as such).

Plato

(c. 427–347 BCE)

GREEK PHILOSOPHER AND WRITER

The Greek philosopher Plato (c. 427–347 BCE) is renowned for his *Republic*, which argues against societies dominated by political turmoil and advocates instead the rule of enlightened and philosophically inclined elites (philosopher kings). As the most prolific interpreter of his mentor Socrates, Plato wrote dialogues characterizing Socrates as a shrewd and versatile interrogator.

Plato was born into a wealthy and aristocratic family that was active in Athenian politics. His given name was Aristocles: “Plato” was a nickname that he received as a result of his broad shoulders, testimony to his youthful love of wrestling. He first sat in the circle of the philosopher Socrates when he was about twenty and remained devoted to his teacher until Socrates’s execution in 399. Afterward Plato traveled for a time, visiting Cyrene, Egypt, and Sicily. His visit to Sicily ended abruptly when Dionysius I, the tyrant of Syracuse, had him deported.

Upon his return to Athens, Plato followed Socrates in the establishment of a philosophical circle. In effect, Plato removed himself from civic life, neither marrying nor participating in political life. Plato’s circle, however, had a more formal existence than that

of Socrates. It met regularly in the grove dedicated to the hero Hekademos, from which it took its name, the “Academy.” This circle, in essence a school if not a university, continued its existence for more than nine hundred years, ceasing its operations only at the order of Christian Emperor Justinian in 529.

Plato’s foundation of the Academy represents the merest beginnings of his influence on subsequent generations. The most prolific interpreter of Socrates, he wrote dialogues in which his teacher is characterized as a shrewd and versatile interrogator. Plato’s Socrates does not offer teaching so much as cross-examine claims to knowledge, tell stories, and muse aloud. In representing Socrates in this way, Plato, perhaps, sought to be true to the spirit of his teacher, who mistrusted certainties and dogmatism. Socrates’s (and therefore Plato’s) philosophy is represented much more as a process than as a product. Although we do not know with certainty whether the philosophical voice of the dialogues is more Socrates or Plato, we can be certain that the voice is an amalgam of the two. The philosophical style that emerges from the dialogues is, however, styled “Platonism.”

The principal feature of Platonism is its idealism. Plato asserted that perceived reality is merely a shadow of truth. Although concepts and objects exist in true and perfect forms, our perceptions

Giovanni Pisano, *Plato* (c. 1280). Marble statue. Duomo at Siena, Italy.

Laws are partly formed for the sake of good men, in order to instruct them how they may live on friendly terms with one another, and partly for the sake of those who refuse to be instructed, whose spirit cannot be subdued, or softened, or hindered from plunging into evil. • Plato (c. 427–347 BCE)

and understandings of those concepts and objects are limited, and thus any attempt to apprehend or describe them is a partial construction, constantly subject to renegotiation, reinterpretation, and reformulation.

As such, Plato deeply mistrusted ideology. As a young man he had expected to enter politics but had been disillusioned by the narrow regime of the Thirty Tyrants (who included members of his family) and even more so by the restored democracy that had proceeded to execute Socrates. Plato's *Republic*, arguably one of the most important philosophical texts ever written, mounts an argument against societies dominated by political turmoil, advocating instead the rule of enlightened and philosophically inclined elites—the so-called philosopher-kings.

After some years Plato took the opportunity to put this philosophical approach into practice. He was invited back to Syracuse by a former student, Dion, a philosopher and politician. Plato became the informal tutor to Dion's nephew, the young tyrant Dionysius II. Dion and Plato both hoped to establish a rational and philosophically consistent regime, and Dionysius II himself initially also seemed enthusiastic. Court intrigue intervened, however, and Dion was banished. Although Dionysius II courted Plato and sought his approval, Dionysius II did not receive it. Instead, Plato went home to Athens, returning to Syracuse only in response to Dionysius II's repeated invitations. Plato stayed for some time, initially hoping to influence Dionysius II and to secure the return of Dion. However, Plato realized that Dionysius II was not terribly interested either in confronting the questions that Plato led him to or in the welfare of Dion. As a result, Plato determined to return home but secured his passage only with difficulty.

Plato's Sicilian experiences led to the composition of an open letter (Letter Seven), which is the most autobiographical document of his that survives. He remained in Athens for the remainder of his life, and at his death was succeeded as head of the Academy by his nephew, the philosopher Speusippus.

Plato's achievement set the tone for much ancient and modern philosophy. Although he has drawn criticism for his elitist vision of an ideal society, he advanced propositions across the entire philosophical spectrum: from aesthetics to education, from mathematics to metaphysics. All subsequent philosophy has, indeed, been likened to a response to this vast body of work. He has also been vastly influential in an unexpected way: his dialogues, the *Timaeus* and the *Critias*, are the basic ancient primary sources for the legend of the lost city of Atlantis.

Plows

Even simple plows made of wood represented a great advance in agricultural technology because they could be pulled by large, domesticated animals, increasing harvests. More complex plows made of iron facilitated the development of feudal society and, to some extent, Western civilization. Plows pulled by motorized tractors are still an integral part of the world's commercial farming system.

Plows allowed humans to use the strength of large, domesticated animals—oxen, horses, water buffaloes, donkeys, and even camels—to cultivate more land than they could using their own power. The amount of grain a family could produce in a year increased accordingly, and where sufficient pastureland could be found, farmers in Eurasia and Africa were able to produce more grain than they themselves needed for food and seed. That, in turn, allowed cities and civilizations to arise. Thereafter, subsequent improvements in plowing methods and other agricultural innovations enlarged food supplies still further; using modern tractors less than five percent of the population of the United States now routinely feeds the rest of the country, with extra left over for export.

In pre-Columbian North and South America, however, domesticated animals capable of pulling a plow were lacking, so when Amerindian civilizations arose, food surpluses to feed cities depended on human labor using digging sticks, hoes, and spades to prepare the soil for planting. But even from smaller fields, Amerindian farmers provided a food surplus because their two principal crops—maize and potatoes—yielded far more food per acre than Old

World grains. But the rural surpluses in the Americas were not as elastic as they turned out to be in the Old World, where breeding stronger animals, inventing better harnessing, improving plow design, and selecting better seeds combined to enlarge agricultural productivity across the centuries.

Scratch Plows

Plows were probably first invented in western Asia. Visual images left by the ancient civilizations (c. 3000 BCE) of Mesopotamia and Egypt first show ox-drawn plows, usually with their most vital working part buried in the Earth. Made wholly of wood, early plows are scarce to nonexistent in the archaeological record, so exactly when and where oxen were first hitched by their horns to a digging stick and compelled to drag it through the soil will never be known. Digging sticks had to be reshaped and made heavier before becoming efficient scratch plows, but once that had been done, the practice of plowing spread very widely. Scratch plows appeared in China along with domesticated cattle, wheat, and barley from western Asia about 3000 BCE, and a cave painting in Sweden dating from something like a thousand years later shows a similar plow in that distant part of Europe.

Scratch plows were light enough for a single man to carry on his back, but for a long time a rope tied to a wooden yoke attached to the horns of two oxen was needed to pull one through the soil. Wooden scratch plows were soon made more durable by using stones shaped into plowshares to slice through and break up the soil. Shaped stones were later replaced by thinner and less fragile iron plowshares throughout Eurasia after about 700 BCE. Wherever scratch plows worked

Greeks use a primitive scratch plow pulled by oxen in this drawing copied from a black-figured Nikosthenes cup, sixth century BCE.

the land, cross plowing—first one way, then again at right angles—was the usual way to prepare the soil for the seed, thus squarish field shapes became standard.

Where rain fell only part of the year, for example in northern China, western Asia, and around the Mediterranean, plowing began when the first rains softened the sun-baked soil and lasted only a few weeks, when planting had to start to give grain enough time to grow and ripen while the rainy season lasted. Wheat, barley, and oats grew wild on the hillsides of western Asia, where the large seeds that made them so nourishing for humans gave them a fast start when moisture returned to the land and allowed them to outstrip the growth of rival plants. But when humans intervened and started to grow grain where it did not naturally prevail, weeds were always a problem. This required early farmers to leave cultivated land fallow, often every other year, so summer plowing could uproot weeds before their seeds formed and so assure a good crop of grain the next season.

In semi-arid climates a single family could cultivate about ten acres of grain by using scratch plows, so surplus food for the support of cities, armies, and governments remained comparatively restricted. But first China and then Europe escaped this limitation in two quite different ways.

Chinese Irrigation

China's way was to create irrigated fields for growing rice. That required an enormous effort to level, dike, drain each field, and regulate the flow of streams to supply just the right amount of water to each field for part of the year and then stop the flow and drain the

field when it was time to harvest the crop. Humans wielding hoes and spades reshaped natural slopes and streambeds to create and maintain such irrigation, and human labor did not cease when the fields were securely covered by a few inches of standing water. Rice seeds had to be planted in special seed beds, watered by hand, then transplanted to the flooded fields as soon as the seedlings had grown tall enough to reach above the surface of the water.

When all went well, irrigated rice yielded as much or more food per acre as maize and potatoes did in America. But the immense amount of human labor irrigation required made Chinese yields per person smaller than Europeans eventually attained. Nor did plows disappear from China when so many spades and hoes got to work. Cross plowing irrigated fields before transplanting the sprouted rice remained usual, and the Chinese soon invented an improved form of moldboard plow for that purpose that turned the soil over in a continuous furrow instead of breaking the surface up into loose pieces as scratch plows did. They also improved harnessing so light moldboard plows, pulled by a single animal, became usual in China after about 300 BCE. But human muscle still did the work of making and maintaining dikes and canals, and the carefully leveled irrigated fields were far too small for heavy, large plows like those Europeans resorted to after about 800 CE.

Overall, the Chinese style of wet rice cultivation was very laborious, but it was so productive and dependable that it spread far and wide from the flood plains of the Huang (Yellow) and Yangzi (Chang) rivers where it first became standard. Fields of irrigated rice gradually spread throughout the rest of historical China wherever sufficient water was available.

This illustration is from a Qing-dynasty (1644–1911/12) version of *Gengzhi tu* (Pictures of Tilling and Weaving, first printed in 1210), a series of twenty-three scenes celebrating the development of farming technology in the Song dynasty (960–1179).

In ensuing centuries, Chinese pioneers, fleeing from overcrowded regions, moved across the landscape like a glacier, altering natural contours and drainage systems more radically than any human population had ever done before.

Beyond China's borders, wet rice cultivation also spread to Korea, penetrated the major river valleys of Southeast Asia and eastern India, and also crossed the seas to Japan and Indonesia. Consequently, something like half of humankind today depends on rice for most of its food, and its cultivation demands far more intensive stoop labor than farmers of northwestern Europe ever had to endure.

Moldboard Plows

Through classical Greek and Roman times, scratch plows with iron plowshares tilled fields of wheat and barley in western Asia, North Africa, and Mediterranean Europe, but year-round rainfall restricted successful farming in northwestern Europe to unusually well-drained soils. On the flat north European plain, extending from France's Loire Valley to the Urals,

dank forests prevailed, and waterlogged landscapes made grain farming marginal. Cattle raising played a prominent role in the north, and where grain could be made to grow, oats and rye replaced the more nutritious wheat and barley of Mediterranean lands because they ripened more quickly. With only a limited supply of food, human populations in northwestern Europe remained thinly scattered amid the forests and could not support cities.

Heavy moldboard plows changed this situation fundamentally by spreading grain fields across the landscape after about 800 CE. Such plows perhaps existed for a long time before they came into wide use. The Roman author, Pliny the Elder, (d. 79 CE) says in his *Natural History* that Celts used a plow with "ears" somewhere in modern France; they may have been ancestral to the medieval European moldboard plow. But a moldboard plow casts the soil to one side only, and that was essential for its eventual success in making northwestern Europe's waterlogged plains into fertile fields of grain. If Pliny's "ears" scattered the soil on both sides of the plow, no such result would have followed. Of course, he may have been wrong about how many ears the Celtic plows had. But we can still be sure that plows with a single "ear," or moldboard, did not come into common use for centuries.

Hundreds of years later, heavy moldboard plows did exist in northwest Europe, becoming common only after about 900. They had a vertical, knife-like coulter thrust into the soil close behind a pair of wheels, located above and ahead of a horizontal iron share designed to slice the furrow and regulate its depth. Then there came a large wooden moldboard lying crosswise behind the share to turn the furrow and roll it over to one side. Lastly, long handles stuck out behind so plowmen could steer the plow and keep the furrow straight.

Four to eight oxen (or even more) were needed to lift and turn the furrows, so no ordinary family could afford such plows. This must have delayed its spread as did the fact that so many oxen could not be turned around easily; plowmen needed several yards of untitled "headland" at the end of each furrow to lift, turn, and reengage the plow. Consequently, these heavy

"March," from Les Très Riches Heures du Duc de Berry, painted by the Limbourg Brothers between 1413 and 1416. This rustic scene of planting and plowing is set against the Chateau de Lusignan, one of the le duc's favorite residences.

moldboard plows could not operate efficiently within the small, square-shaped fields suitable for scratch plows. They also needed a team of several men to control the oxen up front and prevent them from tangling the harness while others behind struggled to guide the plow on a straight and even course. Several families, in short, had to pool resources, each contributing an ox and one or more men to work the plow.

Draining the Fields

Yet when field shapes were altered to allow animals and men to pool their efforts on the necessary scale, the effect was extraordinary. That was because moldboard plowing had the effect of draining surplus

water from northwest Europe's plains, almost accidentally. By turning furrows one way going and the opposite way when returning all day long, plow teams created a long narrow strip that became what we call an acre, eventually defined in English law as 660 feet (221 meters) long and 66 (22 meters) feet wide. Each time a field was plowed, the moldboard rolled the furrows toward the center of each acre, thus creating a raised "land" with lower "baulks" on either side and draining each "land" quite effectively. When years of plowing raised the lands inconveniently high, furrows could be rolled downward again simply by reversing the plowing pattern.

As they spread, therefore, moldboard plows powered by animals reshaped the north European plain almost as drastically as hoes and spades changed China's landscape. Each day's plowing lay alongside another acre to be plowed the next day, thus creating large open fields around each village. European farming still required human hands to sow and reap, but that was done by separate families. To begin with, newly plowed long acres were assigned to each member of the plow team in turn, so each family would have access to more or less equal amounts of land. But rights to each acre soon became hereditary, and before long different families came to possess different amounts of land, and some villagers became landless and had to work for hire.

Year round rainfall permitted European moldboard plows to keep going most of the year, plowing down weeds in summer on fields left fallow, preparing others for sowing in the fall and in the spring. Working year round, except when sowing, reaping, or hay making (and during the frosty twelve days of Christmas), European plowmen were able to cultivate as much as 30 acres per man, roughly three times as much as seasonally restricted scratch plowing allowed. That assured larger surpluses of grain in most years than scratch plows yielded.

Western Civilization

It is not surprising, therefore, that by about 900 CE moldboard plows started to spread rapidly, and, as

forests were cleared, population and wealth multiplied in northern Europe. This coincided with the end of Viking raids, and it is very probable that the initial establishment of long acres and open fields depended on the disruption of older patterns of rural life in France and the Rhineland by Viking raiders. It is easy to imagine how a handful of survivors, emerging from the forests to find almost everything gone, might be willing to forget about older property lines and pool resources to form plow teams while accepting the orders of military men who offered them protection in return for a share in the harvest. At any rate, the open fields did support a class of armored knights from the beginning, and when they became thick enough on the ground, even a handful of knights could arrive quickly on horseback and repel a Viking ship's crew quite easily. As a result, raids came swiftly to a halt. Thereupon villages surrounded by open fields, together with knights, feudal overlords, and increasingly populous towns soon created a distinctive medieval society and civilization in northwestern Europe.

The heartland of moldboard agriculture lay between the Seine and Elbe rivers and extended eastward toward the limits of German settlement. Scratch plows remained standard in Mediterranean lands. Further east, diminishing rainfall and frozen soil in colder winters made moldboard plows only marginally worthwhile. Most of Scandinavia, Ireland, Wales, and western Scotland remained too cool and moist for grain to ripen in most years. So French, German, and English populations were the main beneficiaries of the open fields and cooperative plowing that created them, and they became the main shapers of what we call European or Western civilization.

Subsequent improvements in plows and agriculture always mattered. The invention of horse collars, for example, permitted horses to supplement and eventually displace slower oxen from European fields after about 1300. New crops, most notably fodder crops—hay, clover, turnips—meant more and stronger animals for plowing and overland transport after about 1600. In the eighteenth century, maize and

potatoes spread across European fields, enlarging the food supply enormously when summer cultivation between the rows of these crops put an end to fallowing. At the same time, Europeans learned from Jesuit missionaries in China how to replace flat, wooden moldboards with curved, iron moldboards, and, in the 1830s, steel plows, fusing plowshare and moldboard into a single piece of metal, began to turn the furrows far more efficiently, thus reducing the force needed to pull the plow. A single man driving a pair of horses could pull such improved plows even when breaking the sod on virgin prairie land in North America and southern Russia.

Industrialization

By then, European settlers had carried their the style of agriculture overseas to the Americas, Australia, New Zealand, and other lands, with whatever modifications local conditions required while the enhanced productivity of European fields sustained an industrial revolution after about 1750 that is still spreading around the world. The principal impact of industrialization on agriculture was the advent of tractors in the 1890s, powered by internal combustion motors. They quickly transformed plowing, planting, and harvesting on a worldwide scale. Enormous plows with multiple shares or disks pulled by giant tractors became capable of cultivating many hundreds of acres in just a few weeks. Such plows, combined with other machines for sowing and harvesting, dwarfed older scales of farming. They swiftly displaced horse power from the fields and provoked widespread rural depopulation in North America, Russia, and a few other lands after the 1920s.

Throughout most of Eurasia and Africa, however, small internal combustion motors attached to various specialized machines began to do some of the work human muscle had performed previously, but, for the most part, public policy and custom preserved something like the traditional scale of farming to the present. Of late, large-scale, tractor-powered plows and other heavy machinery have shown an unexpected vulnerability when fuel prices rose sharply

after 2007. Such price fluctuations surely suggest that present methods of plowing and other agricultural work will change very rapidly in times to come, just as they have been doing around the world for the past century or more.

Political Thought

Political thought reflects and debates about the functioning of the state, or processes within it, that provide a state's structure and impact the public it serves. Traditionally, according to ancient Greek political theory, the term *politics* has been considered the highest realm of human affairs, the art that integrates all other pursuits.

Politics as a sphere of human concern has typically been understood in two ways. In a minimalist definition, politics is the realm of the state, of the institution that in complex societies enjoys a monopoly on the legitimate use of force in the territory it controls. Politics thus revolves around efforts by individuals and groups to gain control over the state, and to exercise the state's ultimate power on behalf of public peace, and some interests rather than others. This minimalist definition, dating back to the German sociologist Max Weber a century ago, tends to hold sway in contemporary political science.

A more substantive, traditional definition has its origins in classical Greek (especially Aristotelian) political theory. That view holds that politics is the highest realm of human affairs, the art that integrates all other pursuits. This means that the state, since it orders society as a whole, also has the ethical purpose of relating the various social functions and kinds of human flourishing to one another, and promoting sound character development among its citizenry. Political thought, more specifically, is normative thinking that goes beyond what politics *is* to what it *should be*. Political thinkers put forth visions of an ideal state, against which one might measure the realities of human self-interest and power-seeking.

World Histories of Political Thought

Various important points of contact lie between political thought and world history. One involves world-historical treatments of how political thought has developed in different settings, and how its unfolding reflects broader influences across space and time. Such treatments can occur on the level of either history of ideas or intellectual history. History of ideas traces the influence of thinkers and modes of thinking upon one another over time, often in isolation from larger social contexts. World histories of ideas might deal with the transmission of doctrines over large expanses of space and time, or with the influence of thinkers in different settings on one another. Intellectual history, by contrast, deals more with the social context and imprinting of ideas. Ways of thinking and the social forces that generate them are probed as layers of social reality, as expressions of or at least responses to larger historical circumstances and processes.

One example of world intellectual history is treatment of the so-called Axial Age, the period of Eurasian history between roughly 800 and 600 BCE. The German philosopher Karl Jaspers coined the term to refer to the common flowering of classical thought that happened during those centuries in the major centers of civilization in the eastern Mediterranean, the Fertile Crescent, India, and China. Whether in religious or philosophical guises, the era saw the emergence of complex "second-order thinking," or what one might call "thought about thought." In contrast to the mythical worldview of earlier cultures, new intellectual elites that had come to power began referring to transcendent sources of truth—God, Natural Law,

Heaven, the Dao, and so on—that existed apart from mere tradition. With this opening of a gulf between the mundane world and a higher order, cultures were reoriented away from imitating the past and toward a critical engagement with the example of pioneering creative personalities: prophets, philosophers, and state founders. In the political realm, the new civilizations began measuring the realities of state and society against ostensibly universal ideals of public virtue and cosmic order. From the standpoint of world history, the Axial Age is a framework for thinking comparatively about intellectual processes that occurred almost entirely independently of one another. The overlap in timing also reflects common world-historical conditions, like the emergence of complex urban societies that could support the kinds of stratification needed for such an intellectual breakthrough.

Notably, the emergence of much of this higher-level thinking, especially on a political plane, involved a kind of exercise in world-historical reflection. Early in the Axial Age, two core areas that generated classical political thought—the eastern Mediterranean and north-central China—were divided into many polities. Leading intellectuals like Plato and Confucius posed questions about politics and human flourishing in a comparative way, using the experience of often radically different political communities as raw material for their reflections. They thought broadly about political diversity and historical evolution, using the Greek city-states and the decay of the Zhou Empire into the warring states as illustrations. This comparative approach gave rise to insights into universal truths about human nature and well-ordered states.

Two main types of sophisticated political thought emerged from the Axial Age, from this new Eurasian experience of complex agrarian societies. One, which we might call *virtuocratic*, reflected the worldview of high-culture intellectuals who were committed to certain orthodoxies of religion or philosophy. Such groups included the Hindu Brahmins, the Confucian literati, the Greco-Roman Stoics, and the priests of the Middle Eastern monotheistic faiths. While their conceptual frameworks differed, they overlapped in seeing society as an arena for the pursuit of virtue and human flourishing. The state had a crucial role to play as the

keystone of a just social order, which placed people in positions suited to their natures. The ideal statesman was a kind of philosopher-king, who held himself to a transcendent standard of ethical truths and cosmic order. The ethical activities of the state unfolded on a plane higher than mere functional performance.

A second stream of political thinking that emerged at about the same time can be called *atomist*. Examples include Legalism in China and Sophism in Greece. From the fact of diversity across communities and eras, atomist political philosophers drew quite the opposite conclusion from their more virtue-minded counterparts. They held that diversity showed there was no objective truth or standard of virtue. Human nature amounted to no more than individual self-interest, the rather pedestrian desire to seek pleasure and safety and avoid suffering. Emptied of any moral content, the atomist vision of the state involved only efficient management, preservation of peace, and practicing hard-headed skills of statecraft. This stream of thought, with its social base in the mercantile and bureaucratic classes, endured until modern times but largely below the surface of respectable political discourse. Thomas Hobbes, the seventeenth-century English political theorist of absolutism, was a more recent voice of atomist statecraft, and paved the way for the more mundane and less virtue-oriented character of modern Western political thought.

All these are examples of how world history can situate the emergence of the major traditions of political thought, inform comparisons across those traditions, and trace long-term continuities and ruptures in thinking about politics.

Political Thought as a Lens for World History

In reverse, political thought can also influence the telling of world history. As a mode of imagining the ideal political community and making sense of large-scale social processes, any system of political thought implies a lens through which its adherents view the past. The term *metanarrative* often describes a story of world history colored by political thought. A metanarrative integrates the happenings of the past

into one simplified tale filled with meaning and with lessons for the present.

Metanarratives often have a religious bent. Religious metanarratives date back to the beginning of the so-called world religions, those universal systems of spiritual insight that emerged from the Axial Age. Since each world religion professes to speak to humanity as a whole, to represent a cosmic order not confined to any one territory or culture, it has had to grapple with the problem of religious diversity. Given its superior access to truth, in other words, how should it think about other world religions? The Hindu approach has typically been to treat religious diversity as merely a variety of paths to the same divine essence. This perhaps avoids the need for a metanarrative about the relative worth of religions, but still integrates doctrinal diversity into one overarching system of meaning. In the social realm, however, premodern Hinduism still saw the hierarchies and ritual practices of the caste system as a superior context for spiritual self-cultivation. Non-Hindus who sought true human flourishing would have to enter the Hindu social order over several generations. In practice, some conquerors and potentates were brought into the Hindu caste system by tracing back fictitious Aryan genealogies for them. The traditional Confucian worldview had some similarities to this system. While the absence of caste purity made entrance to Chinese civilization easier for outsiders, entry was still very much a one-way process of *laihua*, of “coming to be transformed.” As the ideal Confucian social order was the supreme expression of virtue, and the emperor the point of contact between heaven and earth, the Chinese polity was seen as radiating outward and potentially encompassing the *tianxia*, the “world under heaven.” “Barbarians” could improve their standing only by ascending the cultural gradient of Confucianization.

Religious metanarratives were most developed in expansionist missionary religions like Christianity and Islam. Founded against the background of earlier Middle Eastern faiths, and colliding with still other religions as they spread around the world, Christianity and Islam have had sophisticated visions of world history and how religious diversity fits into it. Both are *narrative* religions, that is, religions with a sense of historical

development centered on events of significance to a spiritual community. Both share a metanarrative of human creation, fall, prophecy, covenants, and eventual redemption, all unfolding within world history. And both draw on this metanarrative to make sense of other belief systems. Other religions that preceded them, like Judaism, have been seen as legacies of earlier stages in God’s intervention in the world. Islamic theology has proved quite accommodating in extending this basis for coexistence to all the major world religions. In the medieval period, when Christian theologians first struggled to find points of contact with revived classical thought and with the newly encountered cultures of the Americas, they fell back on Natural Law. Natural Law, while only truly fulfilled with knowledge of Jesus Christ, still could be seen as informing all religions and ways of life. It denoted the innate sense of ethics and the striving toward God that even non-Christian societies and religions reflected. For both Christianity and Islam, these metanarratives tied in with practical political arrangements of tolerance and coexistence. In medieval custom, nonbelievers often enjoyed toleration as residues of life before the true religion, though the grand vision of history implied their eventual absorption once their consciences allowed it. Islamic civilization developed elaborate mechanisms of incorporation, in which non-Muslim minorities enjoyed a good deal of social and political autonomy, resting on the idea of a contract of protection that dated back to the early conquests.

Metanarratives of world history have also served political purposes in modern times. Four in particular deserve mention. The first has been called a “Whiggish” theory of history, after the liberal Whig party of eighteenth-century Britain. The gradual constitutional development of the English monarchy, and the growing power of merchants and others of liberal temper, gave rise to the notion that history had been unfolding toward a built-in goal of liberal enlightenment. This metanarrative was transferred to North America, including the United States after its founding as a “great experiment.” As Whiggish historians would have it, the story of the Anglo-Saxon peoples, both in medieval and early modern English experience and in the triumph of the

colonies, was one of divine favor and ever-expanding liberty. In the twentieth century, this metanarrative gained a broader scope, in western Europe and even beyond. During the Cold War, the Whiggish view of history merged into a “Plato to NATO” metanarrative. This saw the contemporary West as heir to a continuous heritage of human freedom over two millennia, and its defender against world Communism. In the present day, an example of Whiggish history is Francis Fukuyama’s book *The End of History*, which predicts the triumph of capitalism and liberal democracy everywhere in the world, as the political system best suited to human nature.

A second modern metanarrative has been Marxist. As Karl Marx (1818–1883) first argued in the nineteenth century, history is driven by class struggle. When technology advances, the economic possibilities it opens up come into tension with older patterns of social and political organization. Eventually societies rupture in revolutions, and new ruling classes rise to power. Thus the major phases of world history succeed one another: slavery, feudalism, capitalism, and eventually socialism and communism. This focus on economic structures and vast impersonal forces can give quite comprehensive and compelling interpretations of world history. One of the strengths of Marxist thought in the early twentieth century was its ability to encompass and explain everything, or at least profess to do so. But it bears noting also that treating the contours of world history as basically inevitable denies much room for human agency. Everything unfolds in its own good time, so hurrying along history as those of a more inspired temper might wish cannot achieve much. Moreover, the eventual triumph of communism rests more on inevitability than on any absolute moral desirability. According to the Marxist metanarrative, all moral standards are products of their time, of the circumstances and interests that they serve.

A third kind of metanarrative is that which affirms a large-scale political identity, typically of a civilization or a nation-state. This use of world history became especially important in the twentieth century, as non-Western parts of the world began finding their

feet within the modern international system. Certain Indian and Chinese metanarratives of world history illustrate this pattern well. To take their place in the world, large and internally diverse countries like India and China have to develop a coherent sense of self and a claim to preeminence despite the momentary triumph of the West. In Jawaharlal Nehru’s 1944 book *The Discovery of India*, the future prime minister laid out what amounted to a metanarrative of Indian history. All currents, no matter how different on the surface, merged together in a single stream of Indian identity, which eventually flowed into the secular, socialist, internationalist India he envisioned. Likewise, Chinese nationalists reflected in the 1920s on what China could keep and what it must abandon in its march to modernity. Many concluded that the Confucian high culture and other traditions had to go, to ensure the modernization and survival of the Chinese race in a Darwinian world.

Whatever the details of these kinds of national or civilizational metanarratives, they have some features in common. They project back onto the past some forerunner of the cultural identity that is supposed to triumph in modern times. They play down internal diversity for the sake of unity. They play up distinctiveness from other cultural centers so as better to affirm a sense of self in the present, and a pride in self-contained accomplishments. Often, the metanarrative comes forward into the last century or two, as a tale of how outsiders (European imperialists in particular) encroached upon a once glorious community. Despite oppression and humiliation, the indomitable spirit of that community eventually broke through again in the mid-twentieth century, and began a process of self-renewal. Sometimes the metanarrative looks forward to a future national or civilizational redemption as a new power center in the world, restored to its proper place by its own efforts.

Postmodernism and the New World History

Finally, a fourth kind of contemporary metanarrative is loosely postmodern. At first glance, it may seem

odd to talk of such a thing, since postmodernism is suspicious of metanarratives and stresses that all identities and meanings in history are constructed and perpetually in flux. But “world history” as largely practiced in Western academia today is heavily influenced by some aspects of postmodernism, and tells tales of the past through a political lens much as the writers mentioned above do. One prevailing emphasis of contemporary world history has been on encounters among cultures, on hybrid identities and transgressions, and on the mixing and matching of cultural packages. Partly this reflects what inevitably would be a theme in any global history, simply given its scale, and the issue for this discussion is less one of accuracy than of relative emphasis. The emphasis goes as far as it does partly because of skepticism toward rival metanarratives of national unity or civilizational superiority. From the past, world historians of this bent strive above all to extract illustrations of pluralism and to call into question any essential boundaries that others might take for granted. This aim maps loosely onto political sympathies for present marginality and the hybrid identities that liberal globalization is producing. Diasporas and transnational migrants and ethnic minorities and the like have not been fully accommodated by the homogenizing national polities of the nineteenth and twentieth centuries. This new approach to world history provides a perspective that serves two complementary purposes, therefore. On the one hand, it undermines what its practitioners see as dominant narratives of exclusionary national identity, thereby opening space for the excluded. On the other hand, it grounds alternative pluralistic social arrangements in a wider range of historical experience, and in doing so adds legitimacy to certain political perspectives in the present. As with all other metanarratives, what we think of as world history also engages profoundly with political thought.

Polo, Marco

(1254–1324)

VENETIAN EXPLORER

The legacy of Marco Polo, a Venetian trader who was one of the earliest Europeans to travel to China on the Silk Roads, includes one of the best-known travelogues in history. He did not write *The Travels of Marco Polo* himself, however, but rather dictated it to a fellow prisoner of war who may have embellished (or omitted) some of what he heard.

In 1271, at the age of seventeen, the Venetian Marco Polo (1254–1324) set out with his father, Niccolo, and his uncle Maffeo on a journey to the Mongol Empire of Khubilai Khan. Marco spent almost the next two decades traveling throughout Asia, trading and working as an official within the Khan's administration. After his return to Venice, Marco Polo was captured in 1298 by the Genoese navy while serving as the "Gentleman-Commander" of a Venetian galley during a war between the Italian city-states. While imprisoned in Genoa, Marco recounted his adventures to his cellmate, Rusticello of Pisa, a writer of romance stories, who had served at the court of Edward I of England. Rusticello's account of Polo's trip, titled the *Travels of Marco Polo*, was one of the first depictions of Asia to appear in the West. Translated into many languages, the *Travels* circulated widely throughout Europe in handwritten manuscript form before the appearance of the printing press. Marco Polo's *Travels* influenced European perceptions of Asia from the late medieval period through to the Age of Discovery in the sixteenth and seventeenth centuries. In 1492 Christopher Columbus carried a copy of the book with him on his voyage west across the Atlantic during his attempt to find a new route

to the riches of Marco Polo's Cathay (as anglicized alternative to the name *China*, especially popular in Europe after Polo used it in his book).

In 1260 the merchants Niccolo and Maffeo Polo joined a Venetian trading mission to the city of Bukhara, located on the famed Silk Roads network in modern-day Uzbekistan. From there they joined a Mongolian embassy and traveled to the court of Khubilai Khan at Kanbalu (Beijing). The elder Polos spent the next several years trading in China until they were ordered by the Khan to return to Venice as his emissaries. When they returned home, Nicollo and Maffeo were instructed to gather a letter from the pope, one hundred Christian scholars as well as a flask of oil from the lamp from the Holy Sepulchre in Jerusalem, and then to return to Kanbalu. When the Polo brothers finally arrived back in Europe in 1269, however, they discovered that Pope Clement IV had died the previous year and had yet to be replaced. Unable to secure the required papal letter or ecclesiastic scholars until a new pope was named, Nicollo and Maffeo left Rome and returned to Venice, where they spent two years awaiting the election of a new head of the Church. Unable to wait any longer and fearing that Khubilai would be angered by their lengthy delay, the Polos, this time accompanied by young Marco, set out on a return voyage to the court of the Mongol ruler. After a brief interruption following the eventual election of Pope Gregory X, the Polos, along with a flask of holy oil and a mere two Christian missionaries left the safety of the Mediterranean world in 1271 to begin their journey across Central Asia.

Marco Polo, a portrait based on a painting in the Gallery of Monsignore Badia in Rome. The story of his adventures along the Silk Roads became one of the best-known travelogues of all time.

Although the missionaries abandoned the party in Armenia, the Polos did return to Khubilai's summer palace at Shandu after a difficult journey through Persia, Afghanistan, Turkistan, and eventually Tibet and the western reaches of China. The Khan was impressed by young Marco and over the course of the next twenty years appointed him to several official positions within his government, including the post of governor of the city of Yangzhou between 1282 and 1285. While in China Marco also visited the southern regions of Khubilai's empire along the Burmese border and much of southern China; he also had a lengthy stay in Hangzhou (Kinsai), the former capital of the Southern Song dynasty. During their time in China, the Polos prospered, but by the late 1280s, they were eager to return home and petitioned the Khan for permission to leave. In the *Travels* Marco claimed that Khubilai had become attached to his Venetian advisors and at first refused their request. At last an opportunity

arose that provided the Polos with a reason to serve Khubilai one last time. The Khan of Persia had lost his wife and had requested that another princess from the same Mongol family be sent to marry him. Since the overland route was extremely dangerous, the Polos volunteered to serve as ships pilots and to escort the princess to Persia by sea. Reluctantly, Khubilai agreed and allowed the Polos to depart, asking that they deliver messages of friendship to the pope and the kings of Europe. Departing in 1292 from the port of Xiamen (Amoy), the Polos traveled past the islands of Sumatra, Java, and along the coast of India before reaching Persia two years later. The following year, they finally arrived back in Venice after being away from home for almost twenty years.

In early 1298, just three years after his return to Venice, Marco Polo found himself serving as a "Gentleman-Commander" or advisor aboard a war galley in his city's navy. At this time Venice was engaged in a war with its rival Genoa over trading rights in the eastern Mediterranean. On 7 September 1298, Marco Polo was captured, along with the entire Venetian fleet, by the Genoese navy. He was then imprisoned in a Genoese jail where he spent the next several months regaling his fellow prisoner, Rusticello, with his tales of adventure and the riches of the Khan's empire. Within a year the war between Venice and Genoa was concluded, and Marco Polo returned home a second time.

Back in Venice, Marco married a woman named Donata, with whom he would have three daughters: Fantina, Bellala, and Moreta. Little else is known of his life from this point on, except that he continued to engage in trade and that he presented a French nobleman with a copy of his *Travels* in 1307. Marco's fame as a traveler spread during his lifetime, although not many people believed his accounts of the riches of China, the sophistication of Asian culture and technology, or the size of the Khan's empire. Most Europeans simply could not believe his tales of paper money, burning black rocks (coal), or cities with populations the size of Western nations. So

incredible were the details in the *Travels* that Marco Polo was often referred to as “Marco of the Millions,” in reference to the number of lies he must have been telling.

In a controversial book published in 1996, the historian Frances Wood argues that Marco Polo was indeed lying and that it is doubtful that he traveled anywhere near China. Along with other critics of Polo's account, Wood notes that Marco failed to mention the Great Wall, tea drinking, the Chinese written script, or the bound feet of Chinese gentry women in his tale. Perhaps these omissions, as well as the more fanciful elements in the *Travels*

involving cannibalism and bizarre sexual behavior, can be blamed not on Marco Polo, but on the chronicler of his adventures, Rusticello. In the end, whether or not Marco Polo ever did make it to the Khan's capital or serve as a Mongol official, is not as important as the fact that his *Travels* inspired generations of Europeans to look beyond their borders and to eventually search for routes to the riches he described.

Population and the Environment

Examples throughout history reveal that the simple formula—more people equals more environmental disruption—does not always apply. Nonetheless, in most circumstances, population growth has brought accelerated environmental change and continues to do so. Since the mid-twentieth century, as human population growth approached its maximum rate, the relationship between population growth and the environment has been the subject of popular and scholarly debate.

The relationship between human population and environment, contrary to popular belief, is anything but simple. In the past half-century, as concern over environmental degradation mounted, popular discussion more often than not emphasized the simple, appealing equation: more population equals more environmental degradation. Although this is true in many circumstances, it is by no means invariably so. Scholars have expended great energy trying to tease out the relationship, but with limited success. The question, in both popular and scholarly debate, has been for fifty years and remains to this day a highly political one, with deeply felt principles involved.

History of Human Population

Efforts to count the number of people in a given territory began in ancient times. The first effort to take a census for an entire polity (Tuscany) was made in 1427. Reasonably reliable censuses date from about 1800 and for most of the world from about 1950. So, reconstructing the history of the entire human

population inevitably involves a hefty amount of inference and educated guesswork. Opinions vary, although there is remarkable consensus on the general trajectory. (See table 1.)

Although it is unclear exactly when humans became humans, when they did there were few of them. Living as hunter-gatherers they were constantly on the move. Carrying multiple small children was a great burden, so early humans checked their fertility by prolonged breast-feeding (which reduces a woman's fertility) and probably checked population growth via infanticide and abandonment. In any case, population growth was extremely slow by today's standards, although it should be understood that today's standards are a bizarre anomaly: for most of human

Various aspects of farming in ancient Egypt are depicted in the Tomb of Nakht, on the West Bank of Luxor.

history population growth in net terms was close to zero, and that population declined almost as often as it grew.

With the shift to food production and more sedentary ways of life, the chief constraint on population growth, the difficulty of carrying around small children, eased. The origins of agriculture date to about ten thousand years ago, at which time there were 4 million (more cautiously, 2 to 20 million) people on the Earth. Where agriculture first took root, in southwestern Asia and the tropical lowlands of the Americas, population growth accelerated somewhat. Birthrates climbed, and although death rates eventually did as well, they did not keep pace. Death rates eventually climbed because agricultural societies acquired new diseases, most of them transfers from herd animals such as pigs, cattle, and camels, that quickly killed people, especially young children. Crowding helped spread such diseases rapidly and promoted others that flourished where human beings lived amid their own wastes.

Gradually agriculture spread throughout much of the suitable terrain on Earth, and most of the human population lived in agrarian societies in which villages formed the social nucleus. Irrigation, especially in Egypt, southern Asia, and East Asia, allowed more productive farming and still denser populations. By 3500 BCE cities began to emerge, first in Mesopotamia. The efficiency of agriculture is extremely variable, depending on soils, crops, tools, and other factors, but as a general rule it can support ten times the population density that hunting and gathering can. For this and other reasons agricultural societies spread fairly rapidly at the expense of the less populous communities of hunter-gatherers.

In agrarian societies, children from the age of about five could perform useful labor, such as tending chickens or weeding gardens. Without the requirement of constant migration, children were more an economic asset than a liability, and so, except in conditions of land scarcity (and even sometimes in such conditions), people tended to marry young and reproduce prolifically. Fertility (here presented in the form of the crude birthrate) reached levels of perhaps 50 per 1,000 per year (about four times as high as the current birthrate in the United States), although rates of 35–40 per 1,000 were probably more typical. Even so, reproductive exuberance barely kept up with the toll from disease and famine, which every now and then reached catastrophic levels, pruning back the population growth of happier years. This, in broad strokes, was the demographic regime of agrarian society, the majority experience of humankind from at least 3000 BCE until 1800 CE.

During that time population grew much faster than it had during pre-agricultural times, although still slowly in comparison to today's growth rates. And there were times when population declined. On local and regional scales, epidemics and famines produced such catastrophes fairly regularly, normally at least once or twice within every generation. On the global scale there were at least two great catastrophes, each of which probably brought global population decline (although the figures are not reliable enough to say with assurance). The first

Aerial view of Mexico City. Urban sprawl is one direct result of population growth. Photo by ardelfin (www.morguefile.com).

of these was the great pandemic of the fourteenth century known as the Black Death, probably a result of the spread of bubonic plague throughout most of Asia, Europe, northern Africa, and perhaps parts of sub-Saharan Africa. It reduced the population of Europe, Egypt, and southwestern Asia by perhaps one-quarter or one-third and on a global level by perhaps one-seventh or one-tenth. In Europe the population took 150 years to recover from the plague's ravages. The second great catastrophe came when the population of the Americas was exposed to Eurasian and African diseases in the wake of voyages made by Christopher Columbus and other explorers. Estimates of the population loss for the period from 1500 to 1650 range from 50 to 90 percent. Because there are no good data on the size of the pre-Columbian population in the Americas, it is impossible to know how large the global effect of this disaster may have been. It might have lowered total global population, although more likely, because there were far more people in Eurasia and Africa

than in the Americas, the total effect repressed world population growth without forcing it below zero.

Accelerating Growth

During the eighteenth century human population embarked on its current spectacular expansion. In several parts of the world epidemics and famines started to recede, and death rates fell. The reasons behind this remain uncertain, although ecological adjustment among pathogens (agents of disease) and their human hosts was surely part of it, as were improvements in food supply and famine management. In some places birthrates also rose slightly. During the nineteenth century world population almost doubled, and then in the twentieth century it almost quadrupled as death rates tumbled. Better sanitation, vaccines, and antibiotics lowered the toll from disease, and much more productive agriculture increased the food supply sharply. In Europe by the 1890s families responded by consciously limiting the number of

births, a reaction that occurred later but more quickly in most other parts of the world. When and where birthrates shrank, population growth slowed; when and where birthrates remained robust, as in much of Africa, Central America, and parts of southern and southwestern Asia, population growth spurted after 1950. Globally, the growth rate peaked around 1970 at about 2.1 percent per year, and population increased by another billion every 12 to 15 years. By 2009 annual growth had declined to 1.1 percent per year, or about 73 million additional people annually. Demographers now expect the world's population to reach 9 or 10 billion around 2050.

For most of history roughly three-fourths of humanity lived in Eurasia. That remains the case today, but the proportion living in the Americas grew sharply after 1750, and the proportion living in Africa leapt upward after 1950. (See table 2.)

Population Policy

People have voiced concern that humanity is too thick on the ground since at least 1600 BCE. Such concern, however, has been rare until recently. Political authorities, when they gave any consideration at all to population, generally took the view that the more people there were within their borders, the better. All the major religions favored population growth, too. This is not surprising: until the last 250 years survival was so precarious that maximizing births

was usually a sensible insurance policy against disaster. But in the mid- and late-twentieth century a few governments began to see matters differently. India and China, by far the two most populous countries, committed themselves to birth control, and in China's case to stern restrictions that between 1978 and 2009 kept the population 300 million lower than it would otherwise have been (it was 1.33 billion in 2009). Other countries in the twentieth century, especially in Europe, sought to increase their birthrates but to very little effect.

Population and Environment

At all times and places the relationship between population and environment is one of mutual interaction. Environmental conditions affect population's trajectory and population growth (or decline) affects the environment.

Historically, the environmental conditions that most influenced population were climate, disease, and agriculture. Major climate shifts, such as the waxing and waning of ice ages, strongly affected human population by changing the proportion of the Earth that was habitable and by changing the biological productivity of the parts not covered with ice. The onset of the last ice age presumably reduced human population, and its end encouraged population growth. Since the end of the last ice age ten thousand years ago, climate change has played only a small

The transformation of habitats resulting from logging, deforestation, and land development has put heightened pressure on many species.

role in determining human population size on the global level.

As noted, the human burden of disease became markedly heavier when and where people took up cultivation, especially settled cultivation, especially when domesticated animals were involved. In tropical lands, except at high altitudes, sustaining dense settled populations was difficult because so many more disease organisms flourished in the warmth. The emergence of cities also created lethal disease environments, mainly because people lived cheek by jowl, communicating infections daily, and because few cities adequately disposed of wastes. So, cities generally, perhaps invariably, were black holes for humanity, sustained only by recurrent migration from healthier, rural landscapes. This situation remained in force until the end of the nineteenth century and in many countries until the middle of the twentieth century. Eventually, mainly through scientific sanitation after 1880, cities became even healthier than rural areas, and one of the great historic constraints on population growth, the lethality of city life, was lifted.

Changes in agricultural conditions also helped to regulate human population by affecting the food supply. Irrigation agriculture, as noted, could support more people than could rainfall agriculture. But irrigation often generated salinization (the accumulation of salts, harmful to plant growth), which over centuries could spoil farmland, as in Mesopotamia, where environmental degradation probably played a role in

episodes of depopulation around 1900 BCE, around 1375 BCE, and before 1250 CE. Over centuries, even over decades, soil erosion could also significantly lower the productivity of agricultural land, which, if not otherwise compensated for, could reduce population. Salinization and erosion could easily affect local and regional populations severely, although at the global level their impacts have always been negligible.

A more recent change in agricultural conditions, the Green Revolution, has had impacts at every scale. Since the 1950s agronomists (agricultural scientists dealing with field-crop production and soil management) have bred new strains of most of the major food crops of the world, making them responsive to heavy doses of fertilizer and timely doses of irrigation water, more resistant to crop diseases and pests, and more suited to machine harvesting. As a result, modern chemicalized agriculture doubled and quadrupled crop yields. The global effect as of 2000 was to increase the world's food supply by about one-third, an essential component of the contemporary surge in world population.

Population growth, or decline, also affects the environment. Just how much it does depends on many factors, including rates of growth, existing densities of population, resilience and stability of ecosystems, the technologies available, and just which aspect of the catch-all phrase *the environment* one chooses to measure. The amount of nuclear wastes around the world, for example, has had little to do with population levels or growth rates but everything to do with technology and politics. Conversely, urban sprawl has resulted directly from population growth (although other factors have been involved).

The circumstances under which population growth proved maximally disruptive to environments were probably those in which initial levels of population were either zero or very low, the growth rate vigorous, and the transformative technologies at hand powerful. The history of New Zealand provides an apt illustration. New Zealand was long

isolated from outside influence and had no human population for millions of years—a sanctuary for species from the Cretaceous era. People first arrived around 1300 CE (perhaps as early as 1000), at first probably only a few. But the Maori—New Zealand’s original settlers—found ample resources in seals, mollusks, and large flightless birds (moas), which they hunted. They burned the forest to make better forage for creatures they hunted and to make room for crops. In the course of a few centuries, they drove the moa and a few other species to extinction and reduced the forest cover of New Zealand by about one-third or one-half. Similar dramatic changes followed upon initial human settlement of other isolated islands such as Madagascar (c. 400 CE) and Iceland (c. 870 CE). Presumably the impacts of initial human settlement in the pre-agricultural past were less pronounced, although the occupation of Australia (about sixty thousand years ago) and the Americas (about fifteen thousand years ago) may have brought on—this is the majority view but by no means a consensus view—numerous extinctions of large and mid-sized mammals. Even without much technology beyond spears and fire, humans, when entering landscapes in which species had no prior experience of human ways, proved highly disruptive.

With more powerful technologies at hand, population growth could be even more disruptive. After 1769, and especially after 1840, New Zealand acquired another settler population, primarily from Great Britain. These settlers had metal tools, which the Maori had not had, grazing animals, and eventually steam engines and the entire panoply of industrial machines. In the span of two centuries, New Zealand’s population went from less than 100,000 to about 3 million, almost all of whom used modern technologies. New Zealand lost most of the rest of its forest cover and many more of its indigenous species (mostly birds), and most of the landscape (discounting inhospitable extremes) became pastureland. Population growth alone, of course, was not responsible for this transformation of New Zealand, although it was crucial. Also crucial was the

existence of overseas markets for wool, mutton, and butter, on which New Zealand’s pastoral economy rested.

Population growth has been least disruptive where heavy labor has been required to stabilize an environment. The best examples of this concern soil erosion. Farmers, when working on slopes, inevitably risk rapid soil erosion unless they can construct and maintain terraces. But that is extremely labor intensive. In the Machakos Hills district of Kenya, for example, early in the twentieth century farmers caused high erosion rates by tilling the soil. They did not have enough people to undertake the backbreaking labor of terrace construction. But by the 1960s population growth had changed that. Farmers built and maintained terraces, stabilizing their soils. A reduction in population density in terraced mountain environments can bring accelerated soil erosion because too few people remain to keep the terracing in place. This happened in the twentieth century in the mountain regions of southern Europe when birthrates fell and young people emigrated. The endless terraces of Java or southern China would be difficult to maintain without dense population.

Population decline destabilized other landscapes as well. In eastern Africa, for example, by the nineteenth century people had learned that to keep sleeping sickness at bay they had to burn off the bush (which reduced the habitat for the tsetse fly that carries sleeping sickness). Sleeping sickness killed cattle more easily than people; it was an economic as well as a health problem. But bush control required labor, and when lethal epidemics broke out at the end of the nineteenth century and the beginning of the twentieth, one result was to make it difficult for people to control the vegetation surrounding their villages. Thus a costly ecological change proceeded: more bush, more tsetse fly, more sleeping sickness. This example, like the terraces of southern Europe, is a case in which an environment, already modified by human action and in a more or less stable state, was disrupted by population decline.

Population, when unchecked, increases in a geometrical ratio. • **Thomas Malthus (1766–1834)**

These examples show that a simple formula (more people equals more environmental disruption) does not necessarily apply. Nonetheless, in most circumstances, population growth has brought accelerated environmental change and continues to do so. In the context of the last half-century, when human population growth reached its maximum rate, the role of population has probably been greater than in previous times (with the exception of local- and regional-scale examples such as New Zealand's initial settlement). Cropland has increased by one-third since 1950, a process mainly driven by population growth. The proportion of land occupied by roads and buildings has grown roughly in step with population and chiefly because of population. The transformation of habitats, including deforestation, the extension of cropland, pastureland, and developed land, has put heightened pressure on many species lately, especially in tropical forests. This pressure, one of the signal environmental changes of modern history, has been driven in part by population growth, although it is difficult to specify how large that part might be.

Population growth also has been a factor in the increased pollution loads of modern history. In cases such as water pollution derived from human wastes, it has been a large factor indeed. But in other cases, such as the pollution of the stratospheric ozone layer by chlorofluorocarbons, population growth played only a little role, and technological change (the invention of chlorofluorocarbons) a much larger one. Thus, among types of pollution, as among environmental changes in general, the degree to which population growth can logically be held responsible varies tremendously from case to case.

In the future it is likely that population will decline in importance as a variable in shaping environmental change. This is partly because the extraordinary pulse of population growth of the past century, and especially the past half-century, will sooner or later come to an end. But this is also because technology looms ever larger as a mediator

between people and their environments, and the pace of technological change seems unlikely to slow any time soon. If global population stabilizes after 2050, as many demographers suppose it will, population shifts locally and regionally will still exert pressures of one sort or another. And it remains possible that because there are already so many people on Earth the addition of another 2 or 3 billion will have a much stronger impact than the addition of the last 2 or 3 billion. That is, there may be nonlinear effects with respect to the consequences of population growth, thresholds that, if surpassed, bring major changes. Observers have predicted catastrophic consequences from population growth for millennia but most consistently (and most plausibly) in the last forty years. It has not happened yet. If it does, it will happen within the next fifty years.

Population Growth

As a species, humans have shown a unique capacity to adapt to their environments in ways that allow them to utilize resources from their surroundings. Thus, throughout human history, long-term population growth has stimulated change, but the demographic trends have themselves been affected by technological innovations, climatic patterns, the actions of states, and the spread of disease.

When seen over large time scales, population growth is one of the most striking features of human history. One hundred thousand years ago, there may have been just a few tens of thousands of humans on Earth. Today, there are more than 6 billion, and they can be found on all continents on Earth (even on Antarctica). No other large animal has multiplied like this (though domesticated species and fellow travelers from rabbits to sheep, from rats to cockroaches, have multiplied, as it were, in the slipstream of humans). So population growth counts as one of the fundamental distinguishing features of human history. Humans have multiplied in this way because they are more innovative than other animals. As a species, humans have shown a unique capacity to adapt to their environments in novel ways that allow them to extract more energy and resources from their surroundings. The source of this capacity for ecological innovation lies within human culture, in the ability, unique to humans, to share and therefore preserve, store, and accumulate learned information generation by generation. Population increase is a natural consequence of this ability, for the constant sharing and accumulation of knowledge has enabled humans to find new ways of exploiting their

environments, so that, unlike other species, they can move well beyond the environments in which they first evolved. Over time, humans have learned to transform their environments in order to exploit them more effectively. As a result of their unique capacity for innovation, humans have managed to feed, clothe, and house increasing numbers of their own species.

Paleolithic Migration and Early Agriculture

Population increase is apparent even in the Paleolithic (foraging) era, though in this era it mainly took the form of a slow but accelerating capacity to migrate into new environments. Humans probably evolved in the savanna lands of southern and eastern Africa, and for all but the last ten thousand years, we have lived as foragers. But the variety of foraging techniques used by humans clearly increased over time. Archaeological evidence suggests that even 100,000 years ago, humans were exploring new environments—in arid regions, for example, or near seashores or in tropical forests (McBrearty and Brooks 2000, 493–494, 530). Then, from about 100,000 years ago, humans began to migrate out of Africa. They appeared in the very different environments of Australia (from perhaps fifty thousand years ago), ice age Siberia (perhaps thirty thousand years ago), and finally the Americas (from at least thirteen thousand years ago). Though we have no direct evidence, we can be sure that these migrations meant an increase in the total number of humans. This remains true even though each particular community remained small, so that contemporaries could hardly be aware that human numbers were increasing.

An aerial view of Levittown, Pennsylvania, circa 1959. Numerous “Levittowns,” the first American suburbs, sprang up after World War II to accommodate the population surge known as the baby boom.

From about ten thousand years ago, as the last ice age was ending, agricultural communities appeared in different parts of the world. Agriculture quickened population growth. Current estimates suggest that there may have been 5 to 10 million humans ten thousand years ago; 50 million five thousand years ago; and 250 million just one thousand years ago. Agriculture stimulated population growth in many ways. Nomadic foragers have a limited ability to increase production from a given area, so they have powerful reasons to limit the number of children too young to walk or forage on their own, and to limit the numbers trying to feed from a given area. Modern anthropological studies suggest that foragers have many ways of limiting population growth, including prolonged breast feeding and even infanticide. But agriculturalists are normally sedentary, so transporting young children is not such a problem. Furthermore agriculture makes it possible to increase the amount of food produced within a given area, so it is possible to accommodate population increase even without migrating to new lands. Perhaps even more important, for farming households in most pre-modern agricultural communities it was important to have lots of children because this increased the available labor. In a world of high death rates (commonly in pre-modern agricultural societies, up to 20 percent of infants died in their first year, and another 30 percent before their fifth birthday), the best way of maximizing

the number of children surviving to adulthood was to have as many children as possible. Such behavior, and the increased resources available within agrarian societies, ensured that populations would grow much faster than in the Paleolithic era.

As in the Paleolithic era, population growth led to migrations, and as farmers migrated they helped spread agriculture around the world. But migration was not the only option, for farmers, unlike foragers, could also create larger and more densely settled communities. Eventually, “intensification” of this kind led to the emergence of communities large enough and complicated enough to be called cities. Seeing these long-term trends was not always easy at the time, because local population gains could easily be wiped out by famines or epidemics. So, to contemporaries, cycles of growth and decline were more apparent than the long-term trend toward growth. Indeed, these cycles provide the central idea of Thomas Malthus (1766–1834), the founder of modern demographic studies: that population growth would always end up exceeding productive capacity so that periodic population crashes were inevitable.

Industrial and Scientific Innovation

In the last thousand years, population growth has accelerated once again as the global human population has risen from 250 million one thousand years ago, to 950 million two hundred years ago, and about 6.8 billion in 2010. There are many specific causes for population increase in given instances, but once again, the most general explanation for this increase is that increasing rates of innovation have allowed humans to produce the food and resources needed to support rapid population growth. Death rates fell in many parts of the world in the last two centuries, partly because of the spread of new crops and improved knowledge about basic sanitation. In the twentieth century, scientific medicine and the introduction of antibiotics have reduced death rates throughout the world. But despite such advances, populations could not have continued to rise if it had not been for the burst of innovation we associate with the industrial

The entrance to a Chinese apartment on a crowded block, June 2004. Multi-storey apartment complexes replace traditional *hutong* courtyards as China's urban population continues to grow.

revolution, which provided the energy, the resources, and the techniques needed to feed, clothe, and supply the rapidly increasing populations of the modern era. Some of the most important new technologies included improved forms of irrigation, the introduction of artificial fertilizers and pesticides, the use of fossil fuels in agriculture, and the breeding of new and more productive varieties of major food crops such as rice and maize. Equally important was the huge increase in available energy supplies made possible by the fossil fuels revolution.

Today we may be in the middle of a new transition, often referred to as the “demographic transition.” Evidence has been accumulating, in some regions for more than a century or two, that as death rates fall and humans become more affluent, more urbanized, and better educated, they have fewer children. By 2000, there was no net population growth in more than thirty of the world's more affluent countries. This trend seems to mark a return to a regime of systematic population limitation, like that of the Paleolithic era.

Population Growth as a Historical Force

Although population growth has been a consequence of innovation, it has also shaped human history in profound ways. The size and density of populations can have a profound effect on rates of innovation, as well as on the structure of society, the power of states, the spread of disease, the health of commerce, and the availability of labor. The following are some of the major types of change in which population growth plays a significant role.

We have seen already that population growth can stimulate migration by causing localized overpopulation. Such migration, in its turn, has been one of the major causes of the spread of agricultural communities throughout the world. The rough calculations of the political scientist Rein Taagepera suggest that the area of the inhabited Earth within agrarian civilizations (a very rough measure of the area dominated by farming) grew from 0.2 percent some five thousand years ago to about 13 percent two thousand years ago, and perhaps 33 percent just three hundred years ago (Christian 2004, 305). While population growth was often the primary trigger for migrations of farmers into new regions, states often backed such migrations because their own fortunes depended on the size of the tax-paying populations under their control. State-backed migrations of this kind have been particularly spectacular in recent centuries as imperial states such as Russia, China, Spain, and Great Britain backed migrations of farmers into previously unfarmed lands in Siberia, Asia, the Americas, and Australasia.

Population growth has been one of the main drivers of increasing social complexity. There is little evidence for significant increases in the size or complexity of human communities until very late in the Paleolithic era. But human societies began to change significantly as soon as population densities started to rise with the appearance of agriculture. Larger, denser communities could no longer be organized through the informal kinship structures that worked well enough in foraging communities, most of which consisted of just a handful of people. Once hundreds

or even thousands of people began to live together in villages and towns, new types of social coordination became necessary to limit conflict, organize worship, and organize collective activities such as defense, or the maintenance of irrigation systems. Eventually larger communities, supported by more productive technologies, allowed for the beginnings of specialization. No longer was everyone a farmer; so specialists had to buy their food and other necessities through markets, which had to be regulated and protected. Cities required even more sophisticated forms of coordination to manage refuse collection and maintain water quality, and for defense. The earliest states appeared, in part, to take over the new organizational tasks that emerged within dense communities; but their power also reflected the large numbers of people they controlled and taxed. In the last two hundred years, population growth has created new and even more complex human communities, so that modern states have had to acquire new administrative and technological skills to manage, tax, and coordinate the activities of many millions of people. All in all, increasing population density counts as one of the main drivers of social complexity in human history.

Population growth and the human migrations that resulted from it have also been a major cause of ecological degradation in human history. There is increasing evidence that this was true even in the Paleolithic era as communities of foragers developed technologies that had a significant impact on their environments. It seems likely that the arrival of humans led to the extinction of many species of large animals, particularly in Australia, Siberia, and the Americas. In Australia and the Americas, it is possible that 70 to 80 percent of all mammal species over 44 kilograms in weight were driven to extinction after the arrival of humans (Christian 2004, 200). But the slow spread of agrarian communities during the last ten thousand years has had a much more profound impact on the environment. Above all, it led to deforestation as farmers moved into forested zones, clearing trees as they went, at first temporarily and then more permanently. Overpopulation and overfarming occasionally caused regional breakdowns in production and the abrupt decline of entire

Chinese one-child policy propaganda poster from 1986, by Zhou Yuwei. The caption reads, “Carry out family planning, implement basic national policy.”

regions. At the end of the third millennium BCE, the populations of Mesopotamia, which lived mainly from sophisticated forms of irrigation farming, collapsed. The cause was probably over-irrigation leading to salinity, which undermined the productivity of the soil. The sudden decline of Mayan civilization at the end of the eighth century CE may also have been caused by overexploitation of fragile environments, leading to an abrupt decline in the fertility of the land.

Finally, though population growth has been a consequence of the human capacity for constant innovation, it can in its turn stimulate innovation by providing new markets and new incentives to increase productivity, and by increasing the number of people contributing to the pool of new ideas. Ester Boserup (1981), a scholar well known for her theories on economic and agricultural development, was a strong supporter of the view that population growth can stimulate innovation, particularly in agriculture. Yet it is clear that such arguments should not be overstated, for there have been all too many instances (some of which are listed above) when overpopulation did not generate new and more productive technologies, but led to social, economic, and demographic collapse. There seems to be a feedback loop between innovation and population growth. But it is not entirely clear which side of this feedback loop is most powerful, and the answer may vary from place to place. Was population growth a cause or a consequence of change? Theorists and governments have been divided on the issue, sometimes arguing for measures to support

population growth, sometimes seeing overpopulation as a prelude to decline.

The debate has raged most furiously in discussions about the Industrial Revolution. Was population growth a cause or a consequence of innovation? There is no doubt that populations were growing rapidly in the eighteenth century in much of the world, or that population growth stimulated innovation by providing cheap labor and expanding markets for food and other basic necessities. Furthermore, in Britain growing populations increased the demand for fuel, which highlighted the shortage of wood and stimulated increasing use of coal, thereby encouraging the fundamental innovations (above all the steam engine) that led to increased use of fossil fuels. Yet it is also possible to argue that innovations in agriculture industry and commerce in turn led to further population growth. Global population growth was caused in part by the exchange of crops, animal species, and human migrants between Eurasia and the Americas (though the exchange of diseases between the continents caused a sharp decline in populations in the Americas). It has also been suggested that in many areas, both in Europe and elsewhere, the spread of new, commercialized forms of production and employment in rural areas (proto-industrialization) may have enabled young couples to create families at an even younger age, whereas previously they might have had to wait until enough land became available to set up a new household and start producing children. Population growth was also caused in part by an increase in the areas being farmed or exploited in new ways, both within major states and in newly colonized regions, usually with the backing of governments. All these factors—the emergence of global markets, the search for new resources with state backing, and the emergence of more industrialized forms of production in rural areas—may have stimulated population growth in the early modern period. In the nineteenth century, the industrial revolution itself stimulated population growth in new ways. New forms of sanitation reduced mortality rates, and artificial fertilizers increased food supplies. Eventually, modern scientific medicines and the spread of

knowledge about sanitation helped drastically reduce mortality rates around the world.

Such discussions show that, however necessary it may be to separate out factors such as population growth as causes of historical change, it is always somewhat artificial to do so. The very notion of “engines of growth” is little more than a crude way of trying to clarify the relative importance of different causes of change. Throughout human history, long-term population growth has stimulated change; but the long demographic trends have themselves been shaped by technological innovations, climatic patterns, the actions of states, and the spread of disease, in a complex feedback cycle that needs to be analyzed instance by instance.

Porcelain was first made in China about 850 CE. The essential ingredient is kaolin, white clay that when fired at an extremely high temperature acquires a glassy surface. Porcelain wares were first exported to Europe during the twelfth century. By 1700 trade in Chinese porcelain was immense, with Ming dynasty wares (characterized by cobalt-blue-painted motifs) highly prized.

Porcelain is a type of ceramic that is white, rock hard, translucent when thin, and resonant when struck. Made from quartz and either kaolin (china clay) or porcelain stone (and later from all three) it is fired at around 1,350°C. The ingredients for porcelain are found in abundance in China but do not exist in West Asia and occur only in isolated deposits in Europe. West Asian potters produced earthenware—made from various clays and fired at 600–1,100°C, while Europeans turned out earthenware and, from the fourteenth century, limited amounts of stoneware, a ceramic produced at 1,100–1,250°C. In contrast, China produced stoneware as early as the Shang period (1766–1045 BCE) and porcelain by the Tang (618–907 CE). During the Song dynasty (960–1279), artisans at Jingdezhen in Jiangxi Province created a superior form of porcelain, made by combining kaolin and porcelain stone.

China had a monopoly on porcelain for a thousand years, until the Meissen manufactory of Augustus II (1670–1733), elector of Saxony and king of Poland, turned out a close facsimile in 1708. Indeed, the success of Chinese porcelain closely tracks that of China's economy and China's international reputation. Triumphant for a millennium, porcelain, Chinese industry, and Chinese prestige all went into steep decline in the last half of the eighteenth century, giving way to

British pottery (which came to overshadow mainland European pottery) and Western imperialism.

Before that historic turnabout, China dominated the international ceramic trade, exporting untold numbers of ceramic vessels to Japan, Southeast Asia, India, western Asia, and eastern Africa. After the Portuguese opened trade with China in the sixteenth century, Europe also became a premier market for porcelain, with perhaps 250 million pieces being imported by 1800. Jingdezhen used mass production techniques to manufacture wares for wide-ranging markets, with a single piece of porcelain passing through the hands of over seventy workers during its manufacture and decoration. Other regions could not compete with the massive Chinese economy, nor could their potters create vessels as lustrous as porcelain. Porcelain surpassed all ceramic ware before it, whether monochromatic whiteware in the Song, or blue-decorated pieces from the Yuan dynasty (1279–1368). In Borneo and Java, local ceramic traditions died out when huge quantities of porcelain were imported. Peoples in the hills of Sumatra and the islands of the Philippines incorporated porcelain into their fertility, divination, and headhunting rituals; they adopted Chinese “dragon jars,” each seen to possess a personality and embody supernatural power, into lineages and passed them down through generations. On the coast of eastern Africa and the littoral of North Africa, porcelain adorned mosques and religious shrines.

In Iran, Iraq, and Egypt in the eleventh century, potters imitated gleaming white porcelain by applying a tin glaze surface to their earthenware. Discontent with the dull result, they used cobalt oxide pigment to paint blue designs on the earthenware. By the fourteenth century, under the influence of Muslim merchants in China and

A pen-and-ink representation of a Chinese porcelain dragon jar decorated with an intricate floral motif.

Mongol rulers in Beijing, potters in Jingdezhen also began producing vessels in blue and white, the ceramic style destined to conquer the world, imprinting them with images of elegance and refinement.

Rulers of Mughal India (1526–1857), Safavid Iran (1501–1722/1736), Mamluk Egypt (1250–1517), and Ottoman Turkey (c. 1300–1922) collected blue-and-white porcelain, while potters in those kingdoms replicated and transformed Chinese designs on their own blue-and-white earthenware. When porcelain reached the West in large quantities after 1600, the same thing happened: the elite amassed blue-and-white porcelain, and potters in Holland, Germany, France, and Italy copied the Chinese ceramics, combining their own traditional motifs with imaginative versions of Chinese pagodas, Buddhist symbols,

and urbane mandarins. At the same time, European princes, influenced by mercantilist doctrine, aimed to staunch the flow of silver bullion to Asia to pay for exotic commodities, including porcelain. In the end, the race to find a formula for porcelain was won by Augustus II, although within a few years, absconding artisans carried the secret to other manufactories.

Still, neither Meissen nor its great competitor, the Sèvres manufactory outside Paris, could compete internationally with Chinese porcelain. That was the achievement of Josiah Wedgwood (1730–1795), the pottery baron of Great Britain. He produced an innovative glazed earthenware, christened “creamware,” that was as durable and thin as porcelain. Equipping his manufactory with steam power and employing mass production methods (modeled on Jingdezhen’s), and being attentive to the latest fashion styles and promotion techniques, Wedgwood aggressively sold his pottery, driving Chinese porcelain from markets around the world. Just as veneration for China in Western intellectual and ruling circles began declining precipitously after 1750, so too Chinese porcelain fell from its age-old pedestal.

Portuguese Empire

The Portuguese Empire was the first and longest lasting of all the empires that western Europeans created. For centuries it provided a forum for an unprecedented variety of cross-cultural interaction, and it owes its longevity to its maritime, trade-based structure.

After Portuguese king Afonso III, who reigned from 1248 to 1279, expelled the Muslims from Portugal, the wars against Islam moved overseas when in 1415 an expedition of glory-hungry Portuguese knights captured—and held—Ceuta, now a Spanish enclave in modern Morocco. That expedition marked the beginning of the Portuguese Empire.

The Empire Expands

Long-standing royal support of maritime activities had culminated in Portuguese Prince Henry the Navigator's promotion of the exploration of the African coast in the new caravel sailing ships rigged with lateens (characterized by a triangular sail extended by a long spar slung to a low mast), which could sail closer to the wind than ever before. By 1435 West African gold was used to reintroduce a gold currency in Portugal, and bases were established on the Gold Coast at Mina (1482) and Axim (1503). In 1498 the explorer Vasco da Gama discovered an all-sea route to India, around the Cape of Good Hope. Two years later the navigator Pedro Alvares Cabral improved the route, avoiding the calm waters of the Gulf of Guinea by skirting the coast of Brazil, which the Portuguese also claimed from Spain under the terms of the Treaty of Tordesillas (1494).

Commercial and missionary expansion, along with a desire for Guinea gold and an alliance with

Prester John (a legendary Christian king and priest of the Middle Ages) against the Muslims, motivated these explorations. As a member of da Gama's crew explained in Calicut (a city in southern India) to two astonished Spanish-speaking Tunisians, "We have come to seek Christians and spices." Although King Manuel I's (1469–1521) assumption of the title "Lord of the conquest, navigation, and commerce of Ethiopia, India, Arabia, and Persia" reflected ambitions more than realities, the monarchy would keep the title for centuries.

1505–1598: Constructing an Empire

A celebrated veteran of the wars against Islam, Francisco de Almeida (c. 1450–1510) left Lisbon, Portugal, in 1505 to serve as India's first viceroy. He wrested an incomplete dominance of Indian Ocean trade from the Arabs and Muslim Indians by defeating their combined naval forces off Diu in western India in 1509. That year he gave up his office to a Crown-appointed governor, Afonso de Albuquerque (1453–1515). During his tenure Albuquerque conquered Muslim Goa on the western coast of India to serve as the Portuguese capital, and captured the entrepôts (intermediary centers of trade and transshipment) of the strait of Melaka on the Malay Peninsula (1511) and the Strait of Hormuz in the Persian Gulf (1515). Having secured these key straits, the Portuguese expanded their maritime empire with a string of permanent forts along the coasts of eastern Africa, India, and Ceylon, which complemented the sizeable lands acquired along the Zambezi River in Africa and in western India. Portuguese victories came as much from their tenacity and superior firearms as

Atlas attributed to Sebastião Lopes, circa 1565. The flags represent the holdings of different empires at the time.

from native rulers' intramural conflicts and disinclination toward maritime battles that earned them no prestige.

Lacking a relative military advantage in eastern Asia, the Portuguese reached commercial agreements with the local authorities in Bengal and China. Although early relations were troubled, through informal agreements worked out in the 1540s the Portuguese began to lease the Macao Peninsula from the Chinese. Regular trade with Japan began in 1544 and was funneled through Nagasaki after 1569. Ships were required to pay tolls at Portuguese ports. This system gave the Portuguese dominance of the spice trade, the principal source of the empire's wealth. At century's end the Estado da Índia (State of India) stretched from Japan to the Cape of Good Hope. Importation of peppers and other spices, as well as silks and porcelains, affected a trade deficit that was balanced with gold bullion and the profit from the "country trade" between Asian lands. Although Brazilian sugar became the first profitable crop export from the Americas, commerce overshadowed agriculture. Amidst the daunting expenses of empire, colonies still had to import foodstuffs along with manufactured goods.

A typical Portuguese vessel sailing to Goa might carry one or two women for every hundred men, and

a Goanese population of mixed heritage soon developed. Albuquerque, in fact, married his men to the local widows created by his invasion. The Portuguese suffered from a labor shortage throughout Asia, and on their merchant vessels a captain and a dozen soldiers (as young as six years old) might be the only Europeans among a crew of African and Asian slaves.

To discharge the universal responsibility that it claimed for non-Christians, the papacy delegated a variety of Church patronage rights to the Portuguese crown. Thus, the Inquisition (a Church tribunal) remained under royal authority, and all missionaries were required to obtain royal approval and to depart from Lisbon. Jealous of its prerogatives, the Crown blocked the development of an overland route to Asia under the protection of the Habsburg ruling house of Europe and icily suggested that unauthorized missionaries be rerouted to Greenland. The mass destruction of Hindu temples in Goa in the 1540s gave away to the policy of denouncing conversion by force even while introducing legal restrictions on non-Christian religions.

When Henry the Cardinal-King (1512–1580) died, his nephew Philip II of Spain pursued an inheritance claim to the Portuguese crown, which he solidified through bribery and an invasion. Philip's successors

The statue of Christ atop Corcovado, 710 meters above the city of Rio de Janeiro, commemorates the 100th anniversary of Brazil's independence from Portugal in 1922.

did not honor his promises to respect traditional liberties, and Portugal would regain independence in 1640. Although the administration of each domain remained distinct, the territories of the joint crown of Portugal and Spain became the first empire upon which the sun never set.

1598–1663: Portuguese–Dutch World War

Battling for independence from Spain, the Dutch came into conflict with the Portuguese through the Spanish-Portuguese union. Although traditionally trading partners with Portugal, the Dutch challenged Portuguese dominance of the spice trade by seeking spices at their Asian sources. From the Dutch attack on Príncipe and São Tomé on the western coast of Africa (1598) to their capture of Portuguese settlements on the Malabar coast of India (1663), the Protestant Dutch and the Catholic Portuguese fought a global war for global trade, not only over the European commerce, but also over the slave trade in Africa, the sugar trade in Brazil, and the spice trade in southeastern Asia. Superior resources and leadership positions awarded for experience rather than social status gave the advantage to the Dutch, although the Portuguese were acclimated to tropical warfare and generally enjoyed greater support from indigenous peoples—a

result in part of Portuguese marriage patterns and the efforts of Catholic missionaries. Even in areas occupied by the Dutch, such as Brazilian Pernambuco from 1630 to 1654, use of creolized (hybrids of mixed Portuguese and indigenous languages) Portuguese languages endured. Hormuz was seized in 1622 by Shah Abbas of the Safavid dynasty of Persia in cooperation with the British East India Company. Melaka, the other vital port in the Portuguese system, fell to the Dutch in 1641 after a long blockade.

1663–1822: Divergences

Dutch victories in Asia shifted the focus of the Portuguese Empire to Brazil, originally little more than a way station for the fleet to Goa. The world's richest known gold deposits were discovered in Brazil in 1695, causing a gold rush and a shift of population from the coastal areas. During the eighteenth century gold would displace sugar as the core of Brazil's economy.

After 1755 equally important changes came from reforms introduced by the Portuguese king's prime minister, the Marquês de Pombal. Pombal formed two chartered companies with monopolies on Brazilian trade. He closed Brazilian ports to foreign ships in order to wean the ports from commercial dependency on Britain. A legal equality was announced

for whites and indigenous peoples, and in 1763 the Brazilian capital was transferred to Rio de Janeiro. In his pursuit of centralized power Pombal butted heads with the Society of Jesus (whose opposition was perhaps more imagined than real), and in 1759 he had the Jesuits deported from Portuguese territories. For similar reasons universities and printing presses were severely restricted.

1822–1999: Independences and Power Shifts

In Brazil heavy taxes and increasingly rigid controls over the gold and diamond industries, designed to favor the interest of Portugal over Brazil, provokes a series of conspiracies among social elites who had acquired Enlightenment-influenced ideals based on rationalism while studying in Europe. These conspiracies rarely flared into rebellion because of fears that revolt would lead to a slave insurrection.

The French emperor Napoleon's 1807 invasion of Portugal prompted the prince regent Dom John (from 1816, King John IV) to flee to Brazil under the protection of the British Navy. This transfer of the court marked the first time in world history that a colony housed the government of the mother country, and the Crown favored Brazil with decrees abolishing mercantilist

prohibitions on manufacturing and opening its ports to all nations—a move welcomed by the market-hungry British. When an 1815 decree designated the empire the “United Kingdom of Portugal, Brazil, and the Algarves,” Brazil enjoyed a status equal with Portugal.

The colonists' enthusiasm for a resident monarch cooled as cheap British machine-made goods flooded Brazil's handicraft market and as the nobles and bureaucrats who accompanied the court brought new competition for jobs. The spark for independence, however, came from Lisbon, when in 1820 liberal revolutionists demanded the return of the king to Lisbon. He appointed his son Pedro regent and returned to Portugal. Seeking a return to a subordinate Brazil tied to Portugal by a commercial monopoly, the revolutionists demanded that Pedro also return. Pedro refused and, acting on his father's parting advice, declared the independence of Brazil on 7 September 1822. Thus, a liberal revolution in Portugal triggered a Brazilian revolution more conservative and less bloody than other independence movements in the Spanish colonies at the time.

The Enduring Afro-Asian Empire

Brazilian independence shifted the heart of the Portuguese Empire to Africa, with smaller possessions

remaining in western India, East Timor, and Macao. A new policy favored African colonial expansion, which would threaten an alliance with Britain that dated back to 1372. In 1886 Portugal obtained French and German recognition for its claims to a trans-African colony extending from Angola to Mozambique, but British rival claims led to an ultimatum issued by the British to the Portuguese in 1890. Caught between proimperial public opinion and the threats of the British Navy, the ultimatum crisis toppled the Lisbon government. Subsequent agreements with Britain (1891, 1899) recognized existing Portuguese colonies, which covered almost one-tenth of Africa. Throughout their African colonies the Portuguese suffered casualties in campaigns against the Germans during World War I. During the 1920s the League of Nations denounced the forced labor practices that had replaced slavery in Portuguese colonies by the turn of the century.

As minister of colonies, António de Oliveira Salazar (1889–1970) in 1930 announced the Colonial Act, which reemphasized the colonial tradition by centralizing administration and unifying the imperial economy against foreign capital. In 1951 Salazar attempted to deflect anti-imperialist criticism by reorganizing the colonies into the “overseas provinces” of a “single and indivisible” state. The regime increasingly directed investment and white emigration from Portugal to the African colonies, thus worsening racial tensions.

Decolonization

After winning independence from the British in 1947, India began pressing claims against Portuguese enclaves on the subcontinent. Portuguese authorities violently responded to nonviolent resisters crossing into Goa from India in 1955, and diplomatic relations were severed. Indian troops seized Goa, Diu, and Daman in 1962.

Salazar’s enduring opposition to decolonization sparked renewed independence movements, troop reinforcements, and expensive wars in Africa beginning in 1961. General António de Spínola, a veteran of these wars, promoted negotiated self-government as

an alternative to continued violence in his 1974 book, *Portugal and the Future*. A 1975 military coup involving General de Spínola followed in Portugal, bringing independence to Portuguese Guinea. All other Portuguese colonies in Africa became independent the next year. The Portuguese withdrew from Angola without formally transferring power to any of the liberation movements that had been active in the country, and a long and increasingly internationalized civil war began. Nearly 1 million people fled to Portugal from the former African colonies, adding a refugee crisis to the already volatile domestic situation.

On 28 November 1975, East Timor declared its independence but was overrun by Indonesia nine days later.

The last of the Portuguese overseas provinces, Macao had lost its economic role to Hong Kong after 1842 and had declared its independence from China in 1849. Its neutrality during World War II made it attractive to European as well as Chinese refugees, who came in even greater numbers after the Communist takeover of China in 1949. Not until 1984, under pressure from the Portuguese governor, did the majority Chinese population obtain the right to vote. Only in 1987 did China agree to assume rule of Macao: following the pattern established by Hong Kong two years earlier, Macao returned to Chinese rule in 1999 under an agreement preserving local autonomy for fifty years.

As the first and longest lasting of the European empires, the Portuguese Empire is notable for its longevity and for its maritime, trade-based structure. Today Portuguese Creole languages continue to be spoken in Africa, Asia, and the Americas. Founded in 1996, the Comunidade dos Países de Língua Portuguesa (CPLP) unites eight Portuguese-speaking countries to promote the language and to facilitate the cross-border circulation of their citizens.

Postcolonial Analysis

Postcolonial analysis is a mode of inquiry into the nature and aftereffects of European colonial rule in different parts of the world, from the Americas to India and Africa. It has emerged since World War II as one of the most dynamic if not controversial modes of inquiry to be articulated in the humanities.

Much thought in postcolonial analysis is of recent origin, having developed during the past century out of the confluence of traditions that are strongly anticolonial, highly theoretical, and interdisciplinary in their orientations. Drawing from an eclectic range of theorists (Homi Bhabha, Jacques Derrida, Frantz Fanon, Michel Foucault, Mohandas K. Gandhi, Antonio Gramsci, Edward Said, and Gayatri Spivak) and intellectual traditions (feminism, Marxism, postmodernism, and psychoanalysis), postcolonial theory has opened new fields of inquiry across diverse disciplines that have reframed the phenomena of European colonialism and its legacies. It continues to critique social inequality and structures of power around the globe, supporting the resistance of subordinated peoples to dominant traditions. Postcolonial analysis tends to be self-consciously critical as it attempts to fashion new forms of cultural and political activity.

Canonical in the development of postcolonial analysis has been the work of Edward Said, whose book *Orientalism* (1978) discussed the ways in which European representations of the “Orient” were responsible for producing enduring stereotypes that have persisted to this day. More recently, postcolonial historians have also been deeply concerned with recording the lives and voices of subaltern (disempowered) peoples.

Drawing from a range of theories spread across disciplines, these subaltern historians have generated a renewed interest in questions of power, inequality, and human agency. But this mode of inquiry has its share of critics. While some have critiqued the possibility of ever writing subaltern histories, others dismiss these postcolonial writers as migrant “Third World” intellectuals enjoying the benefits of a restructured capitalist global economy. Still others criticize postcolonial theorists for their use of incomprehensible language and excessive indulgence in intellectual gymnastics.

Postcolonial Analysis and World History

Postcolonial writings examine a range of topics that interests world historians, such as colonial encounters, diasporic (scattering) and immigrant experiences, and modern capitalism and its discourses of development. In such writings postcolonial analysts tend to unpack long-held views of scholars to reveal the nuances that are inherent in any historical phenomena but that are often ignored by others. For instance, postcolonial writings have contributed significantly to broadening our understanding of long-studied phenomena such as European colonialism. Colonizer-colonized interactions are no longer seen as colliding worlds but rather as complex, hybrid, and sometimes contradictory flows that shape both the colonizer and the colonized. Postcolonial writers have been careful to take into account the role of class, gender, race, sexuality, ethnicity, and nationality in explaining historical processes. Writers have given critical attention also to how Europe’s intellectual legacies (eighteenth-century Enlightenment thought

British and Indian officers of Fane's Horse, a cavalry serving in China during the Second Opium War. From *The Illustrated London News*, 1860.

based on rationalism, science, the modern state, and colonial knowledge) have shaped our world, engendering dangerous stereotypes, misrepresentations, and inequalities. Writers have given special attention to questions of religious conversion, Western science and education, travel writing, literature, and nationalism.

Postcolonial analysis is a valuable addition to the repertoire of approaches being used by world historians to conceptualize global flows, processes, and connections across time. It has provided world historians with a repertoire of tools for analysis drawn from feminist studies, literary criticism, Marxism, philosophy, and psychoanalysis. Postcolonial analysts study global phenomena such as imperialism, colonialism, decolonization, capitalism, world systems, nationalism, and migration not only in terms of neatly bounded nations, culture regions, civilizations, time periods, and abstract processes but also in terms of complex flows that embrace a wide range of actors across societies and time periods. The advent of subaltern studies approaches has impressed on world historians the need to critique structures of power and social inequalities and to recognize the presence of disempowered and subordinated groups (women, indigenous peoples, peasants, tribals, low castes,

gays and lesbians) throughout the history of the world. Recent postcolonial writers have taken a philosophical turn in their attempt to critique the very discipline of history—especially its intellectual debts to Western thought. These writers seek to include alternative understandings of the world that do not conform to the standards of Western reason or modern disciplinary conventions.

Implications

Yet this focus on complexity and agency in the study of historical processes has not always transitioned neatly to the study of large-scale processes. Perhaps what distinguishes postcolonial analysis from other forms of writing in world history is its reluctance to produce grand theories or analyze large-scale processes and instead to focus more on specific texts and historical situations concerned with the politics of identity formation and the agency of human beings. With many of its creators themselves migrants to the “First World,” it is not surprising that postcolonial analyses are particularly interested in the dynamics by which social identities based on class, caste, gender, nationality, ethnicity, race, and sexuality are informed and unsettled by global phenomena such as capitalism, colonialism, migration, and international politics. Postcolonial writers frequently engage in self-criticism, or auto-critique, and so postcolonial narratives can seem to break up no sooner than they take shape.

Nevertheless, postcolonial analysis has contributed significantly to the study of world history by cautioning against the development of simplistic macro (large-scale, general) frameworks and categories that usually end up losing sight of the variety of historical actors and the nuances that make up global processes. World history practiced in this vein becomes theoretically sophisticated, thematically focused, and self-critical, its dominant narratives and grand theories constantly breaking down to reveal the world full of differences, contradictions, and variations. Although we cannot yet see the full impact of these trends in world history, postcolonial analysis continues to offer

*History must be written of, by and
for the survivors.* • **Anonymous**

one of the most exciting frameworks for cultural study and will invigorate the study of world history for some time to come.

Postmodernism

Postmodernism can be more easily described by concepts it resists or denies—universal truths, ideas, activities, narratives, and definitions, as well as notions of rationality, authority, progress, clarity, and objectivity—than by a theory its proponents hold in common. The most radical postmodernists see world histories as being no more than rhetorical constructions fashioned from Western concepts of space and time.

In *The Postmodern Condition* (1984), the philosopher Jean-François Lyotard (1924–1998) described postmodernism as “incredulity towards metanarratives” (Lyotard 1984, xxiv). While not aimed specifically at world historians, this observation—like many others by postmodern thinkers—has serious implications for the field of world history.

Origins and the Problem of Definition

Trying to define postmodernism is rather like trying to get a uniform and cohesive set of demands from globalization protestors. The adjective *postmodern* is applied to a varied assortment of nineteenth- and twentieth-century thinkers, including Friedrich Nietzsche (1844–1900), Martin Heidegger (1889–1976), Theodor Adorno (1903–1969), Walter Benjamin (1892–1940), Max Horkheimer (1895–1973), Jacques Lacan (1901–1981), Roland Barthes (1915–1980), Gilles Deleuze (1925–1995), Michel Foucault (1926–1984), Hayden White (b. 1928), Jean Baudrillard (1929–2007), Jacques Derrida (1930–2004), Félix Guattari (1930–1992), Luce Irigaray (b. c.1932), Fredric Jameson (b. 1934), and Julia Kristeva (b. 1941). It is difficult to identify overlaps in these thinkers’ ideas,

let alone any clear program or agenda. This is because they are resistant to, and incredulous of, universal truths, ideas, activities, narratives, and definitions as well as notions of rationality, authority, progress, clarity, and objectivity. Postmodernism thus entails a questioning of the grounds and forms of knowledge claims, including those made in histories and world histories. Postmodernism shares affinities with, but is not synonymous with, poststructuralism. Poststructuralism challenges the view that linguistic structures such as signifiers (sounds or scriptive symbols or words) are stable and reflective of the mind and reality.

Postmodernism is known to most historians through the strong reactions it provokes in those opposed to it. The historians Gertrude Himmelfarb and Arthur Marwick see postmodernism as incompatible with historical study; Keith Windschuttle has connected it with the “killing” of history, and Geoffrey Elton has concluded that it is the “intellectual equivalent of crack” (1991, 41). While extreme, these comments reveal an understanding of the extent to which postmodern claims undermine many of the methods and ideas that give shape to historical research and writing. To postmodern theorists such as Keith Jenkins, notions of truth and objectivity and indeed the very activity of writing history are comforters that need to be dispensed with. Others have struck a more conciliatory chord, suggesting, as Beverley Southgate has, that history be reconstructed to “incorporate rather than repudiate postmodernist ideas and ideals” (Southgate 2003, 29).

World History and Postmodernism

Postmodernism unmasks world histories as constructions—not descriptions—of the world by

Postmodernism is modernism with the optimism taken out. • **Robert Hewison (b. 1943)**

and for particular groups. They are “grand,” “master,” or “meta” narratives that legitimate certain ideals and gloss over conflicting views and discontinuities. Traditionally that has meant the adoption of a Eurocentric position: that is, events and spaces are named, organized, and judged in line with European ideas and ideals. Framed thus, world histories convey the message that European civilization is the epitome of a modern civilization, that European culture offers a model that other cultures should and will aspire to emulate. In questioning the privileging of a single view of the past—whether Eurocentric or any other “centric” view—postmodernists argue that all we are left with are multiple and often contradictory perspectives. That endpoint appears to be incompatible with the project of researching and writing world history, as that project demands the selection, arrangement, and synthesis of historical experiences.

Adding to the challenge posed by postmodernism, poststructuralism questions whether world histories may be linked back to authors or even to a real historical world. As writers are shaped by the system of language they are born into, world histories should not be studied for their creators’ intentions but for traces of that system through the examination of other texts (intertextuality). Opinion is divided about what texts will be considered relevant in studies of intertextuality: some writers focus on contemporary works from the same genre, whereas others cast their studies much wider, crossing spatial, temporal and genre boundaries. In the wake of the death of the author, as the literary critic Roland Barthes calls it, comes the birth of the reader, who writes and rewrites meaning. This deconstruction is extended even further in the writings of the philosopher Jacques Derrida, who denies that even readers can be a source of meaning and who characterizes the search for meaning as movement in a closed maze of mirrors. In Derrida’s view, signifiers do not refer to phenomena outside of a system of language: They only refer to other signifiers in an endless chain of signification.

Responses to Postmodernism

Given the radical implications of postmodernism for the field of world history, it is surprising that few writers have addressed the topic. Nor is it clear that postmodernism has been the major stimulus for the reduced scope of new world histories and the currently lively discussion on Eurocentrism. The rise of gender history and postcolonial and world systems studies, as well as concerns about the practicalities of world history education may also be credited for these developments.

Writings on postmodernism and world history focus mainly on metanarratives that dissolve the roles of nations and historical agents. Addressing the latter, for instance, the psychologist Lewis Wurgaft has described the writing of national and world histories as a form of psychological projection intended to ensure “narcissistic equilibrium” (Pomper, Elphick, and Vann 1998, 195). The historian Stephen Greenblatt has called for the creation of world histories in which cultural difference and homogenization oscillate and deny one another mastery. Kerwin Lee Klein (2000, 275), also a historian, has taken a more critical stance, suggesting that Lyotard’s distinction between “master” and “small” narratives “carries over the venerable antinomy of people with and without history,” which postmodernism tries to escape. Jerry Bentley, who edits the *Journal of World History* (and is one of the editors of this encyclopedia), has also been critical of postmodernism, arguing that the reduction of history to discrete micronarratives has led to a neglect of cross-cultural interaction. In response, he has posited a large-scale empirical narrative from which themes like population growth are inducted, not imposed. But Arif Dirlik, a historian whose research focuses on China, argues that Bentley’s inducted empirical themes are fashioned out of Western concepts of space and time—as seen, for instance, in the naming and division of the continents—even in the most inclusive new world histories. To Dirlik’s view, world histories are rhetorical constructions, and world historians have yet to grasp that due recognition of differences “may

mean the end of history as we know it" (Stuchtey and Fuchs 2003, 133).

The opinion of postmodernist writers on what will (or should) occur after this death of history varies, and most do not say anything at all on the subject. This is because dictating an "after" is much the same as presenting an endpoint, the concept of which is too universalist for postmodernism. Some may see humans engaged in emancipatory aporia (living lives of radical undecidability, unrestrained by moral, and historiographical norms), whereas others see us engaged in conversations unrestrained by purpose and endpoint.

Potato, Sweet

Sweet potato grows in a wide range of environments, but it is a very important food crop in parts of the tropics and subtropics. The edible tuber, rich in vitamins A and C, is the most important part of the plant, but the leaves are eaten in some places. It is a highly productive crop and returns a large amount of food energy for the labor expended in growing it.

Sweet potato is the seventh most important food crop in the world, after maize, rice, wheat, potato, cassava, and barley. The tubers, a significant source of food energy, are rich in vitamins A and C. Sweet potato is culturally important in societies as diverse as Japan, southern United States, and New Guinea. Large quantities are fed to pigs in many countries. Sweet potato grows in a wide range of environments: from sea level up to 2,800 meters (near the equator); from about 40° north to 38° south (in New Zealand); under a wide range of soil moisture conditions; in locations with a mean annual rainfall from 750 to over 5,000 millimeters; and on a wide range of soil types. In the western Pacific, long-term cultivation of sweet potato at the same site often results in a change in vegetation from forest to a mix of woody regrowth and grass, or even to grasslands. Soil fertility is also reduced by long-term continuous cultivation. In low intensity agricultural systems—where the cropping period is short and the fallow period long—these changes do not occur.

Sweet potato was domesticated thousands of years ago in tropical America, in either Central America or western South America. Polynesian voyagers took it from its South American homeland to

the Pacific Islands about one thousand years ago. It became an important food at the extremities of Polynesia in Easter Island, Hawaii, and New Zealand before the era of European exploration. Christopher Columbus brought it back to Europe from the Americas in early 1493. Portuguese travelers then took it to Africa, India, and to Southeast Asia in the sixteenth century. It was spread from eastern Indonesia (Maluku) into New Guinea by local travelers.

Sweet potato arrived in the New Guinea highlands about 300 years ago. The new crop had a major impact there, allowing greater human populations (and pig populations, too, because humans fed their pigs great quantities of sweet potato) in high-altitude locations (2,200–2,800 meters), as well as probably resulting in a revolution in economic and social organization.

World production is now dominated by China where some 85 percent of tubers are grown. Another 10 percent of world production occurs in Papua New Guinea (PNG), Uganda, Nigeria, Indonesia, Vietnam, and Japan. Sweet potato is a significant food in three regions where consumption by people and pigs is high. These regions are the western Pacific (Solomon Islands, Papua New Guinea, and Papua [Indonesian New Guinea]); southern China; and eastern Africa (Rwanda, Burundi, Uganda, and Tanzania). It was also a significant food item in parts of eastern Asia until forty or fifty years ago, particularly in Taiwan and Japan. But consumption has decreased in eastern Asia and sweet potato is associated with poverty and harsh wartime conditions there.

Sweet potatoes sprouting. Photo by June Oka (www.morguefile.com).

In the western Pacific, the quantity produced per person has expanded greatly over the past sixty years. It is the main staple food in the Solomon Islands, parts of lowland Papua New Guinea, and all of the New Guinea highlands (both in PNG and Papua). In PNG, sweet potato now provides 63 percent of food energy from locally grown foods, compared with 45 percent some fifty years ago. The expansion of sweet potato, and other new crops from the Americas, has facilitated intensified land use in the western Pacific and has allowed two generations of a rapidly increasing population to be fed with minimal disruption.

Potatoes

First domesticated about 8,000 years ago in the Andes, potatoes rank fourth among twenty-first-century food crops—after rice, wheat, and maize. The potato has sustained whole populations in times of war, provided the “fuel” to energize the workforce behind the Industrial Revolution, and played a small yet significant part in the transformation of Chinese society and economy since the 1980s.

The potato (*Solanum tuberosum*) first figured in human history as the principal food of the people living high in the Andes of South America. Thousands of wild varieties of potatoes grow today throughout the Andes from Columbia in the north to Chile and Argentina in the south, but the place they were first domesticated about 8,000 years ago was almost certainly around the shores of Lake Titicaca located between Peru and Bolivia, some 12,500 feet (3,812 meters) above sea level.

At that elevation temperatures remain cool even under a tropical sun and at night freezing temperatures are common throughout the year. But narrow fields bordered by ditches filled with sun-warmed water from Lake Titicaca raised air temperatures sufficiently to keep potato plants from freezing at night. Resulting harvests could be stored for years by freezing them at night before soaking them in water and then drying them in the sun to make what the Spaniards later called *chuno*.

From the Andes to Europe—and Beyond

Chuno was what fed the laborers who built the cities and roads of the Inca Empire and its predecessors, and

when a handful of Spaniards conquered Peru in 1532, fresh potatoes and *chuno* continued to support the thousands of indigenous laborers they conscripted to work on their estates and in silver and mercury mines. The silver mine at Potosi (modern Bolivia) produced so much silver between 1545, when it was opened, and 1650, when the richest lode was exhausted, that a flood of silver inflated prices throughout Europe and Asia. Everywhere people were sure that wicked greed was responsible for the rapidly rising prices that disrupted market relationships and made wages lag behind the cost of food. Resulting suffering embittered Protestant–Catholic conflict in Europe, Sunni–Shi’a struggles among Muslims, and provoked Buddhist rebellions in China. Without potatoes to feed Peruvian miners, such an unprecedented quantity of silver could not have raised prices so rapidly. This was the first time that potatoes played a world-transforming role in human affairs.

But it was not the last, for as potatoes spread to other parts of the Earth they enlarged local food supplies and provoked population growth that disrupted older social relationships as much or more than price inflation had done. Sometimes, as in Ireland, potato-eating populations became desperately poor and vulnerable to crop failures; growing populations elsewhere, supported only in part by potatoes, provided manpower for factories and mines and helped to launch what historians call the Industrial Revolution, first in Europe, then around the world.

Exactly when and how potatoes first got to Europe is unrecorded. But since Spanish ships along the Pacific coast could not at first provision themselves with familiar European foods, locally available potatoes and other substitutes had to be used to feed sailors on

Jules Bastien-Lepage, *October: Gathering Potatoes* (1879). National Gallery of Victoria, Melbourne.

their return voyages to Spain. Soon after the conquest, it is certain that some of them found leftover potatoes worth carrying ashore as curiosities and for planting, both in the Azores and in Spain. The first written records from the Canary Islands date from 1567, and records kept by a hospital for the poor in Seville, Spain, show the purchase of a few pounds of potatoes in that year and of larger quantities in later years. We cannot be sure, however, whether these entries referred to *Solanum tuberosum* or to sweet potatoes. Complete certainty begins only after two potatoes

reached a botanist named Carolus Clusius in 1588; when he finally published his *Rariorum plantarum historia* (Antwerp, 1601) he reported that the potatoes he described in precise detail were already common in Germany and Italy. Earlier, in 1597, an English botanist named John Gerard published a woodcut of the new plant, saying erroneously that it had come from Virginia. Since the plants described by Clusius and Gerard had differently colored flowers they must have been separately introduced into Europe by anonymous sailors, who knows how much earlier.

Most of Spain was too dry for potatoes to grow without irrigation, but in the northwest Basque country rainfall sufficed to assure a good crop. By 1600 or before Basque fishermen had come to depend on the new food; these fisherman introduced potatoes to western Ireland, where they were accustomed to stop for rest and refreshment on their way to and from the Grand Banks off Newfoundland in North America.

Potatoes took hold in Ireland only half a century later when Oliver Cromwell's armies conquered and banished Irish Catholics to the westernmost province of Connaught (1662), while parceling out the rest of the country to Protestant English landowners. In crowded Connaught the fact that an acre of potatoes could feed a family for a year, if supplemented by milk from a single cow, made survival possible for the banished Irish. But since English laborers refused to accept a potato diet, throughout the next century or so the English landlords in the rest of Ireland found it cheaper to employ Catholic Irishmen than to provide the bread Englishmen demanded. Hence the rural population became Catholic once again, living almost wholly on potatoes, and deeply alienated from their Protestant landlords and employers.

Different circumstances governed the spread of potatoes on the European continent. Initial prejudice against a food so different from grain was widespread; but wherever marching soldiers confiscated grain from peasants, as was customary, prejudice against potatoes quickly faded away, since simply by leaving the tubers in the ground and digging only enough for day-to-day consumption, a family could survive even after all their grain had been seized and carried away.

Potatoes in Wartime

During the Eighty Years' War in Europe (1568–1648), Holland and Belgium became the major battleground between 1576 and 1648. There Spanish soldiers fought against the Protestant Dutch; after the Spanish Armada met defeat in 1588, the only way Spanish armies could reach that theater of war was by sailing to northern Italy and then marching over the Alps and

down the Rhine River valley. This so-called Spanish Road was where European peasants first began to raise potatoes in their private gardens as a life-saving insurance against recurrent grain seizures by Spanish soldiers on their way to war.

Seed potatoes (potato tubers grown for their buds, which are used to start new plants), and knowledge how to plant and cultivate them, presumably spread from village to village and from person to person leaving no written record. Subsequent wars waged by the French king Louis XIV (1643–1715) in the Rhinelands probably spread potatoes still more widely for the same reason and in the same unrecorded fashion.

But as long as potatoes were confined to gardens traditional methods of open field cultivation kept them marginal to European agriculture as a whole, however important they became for those who used them to escape starvation. Only after 1740 did potatoes move into European open fields, and we happen to know exactly how that occurred. During the War of the Austrian Succession (1740–1748) youthful Frederick (later the Great) of Prussia noticed that even prolonged campaigning in the Rhinelands, where Spanish soldiers once had trod, did not reduce local peasants to starvation, and he quickly discovered why. He decided that Prussian peasants needed the same cushion against military ravages; after becoming king of Prussia in 1740 he ordered local officials to find seed potatoes and show peasants how to grow them, no longer just in gardens but in fallow fields.

For centuries in northern Europe, half to one-third of all cultivated land had been left fallow and plowed in summer to kill weeds before their seeds had formed. This was the only way grain could outgrow weeds and yield a satisfactory harvest the following year. Potatoes also had to be hoed to keep back weeds. That meant they could provide an abundant supply of excellent food while weeds were kept under control at the same time, with absolutely no diminution of grain supplies, but at the cost of a lot of extra work. Extra food, however, made it easy to feed more than all the people needed to hoe potato fields, and as Frederick himself soon found

Without the potato, the balance of European power might never have tilted north. • Michael Pollan (b. 1955)

out, the crop also assured their survival in wartime as never before.

During the Seven Years' War (1756–1763) French, Austrian, and Russian armies invaded Prussia year after year and seized grain as usual wherever they could find it. But by then, despite initial local reluctance and occasional resistance to Frederick's orders, enough potatoes were growing in Prussian fields to feed everyone, thereby keeping the Prussian rural population and army safely in existence until a new ruler in Russia changed sides, the French withdrew, and Austria reluctantly decided to make peace with Frederick, who thus suddenly emerged victorious against seemingly overwhelming odds.

During the war the invading armies soon noticed how potatoes helped Prussians to survive. Other European governments quickly decided that they too needed potatoes as a resource against wartime famine. Accordingly, wherever moisture was sufficient for potatoes to flourish—that is, across the north European plain from the Loire River in France to the Urals, and beyond into Siberia—they soon began to take over fallow fields on a massive scale.

Since an acre of potatoes produced up to four times as many calories as an acre of grain, European food resources started to rise rapidly; population shot upward, as did manpower for the Industrial Revolution that raised European wealth and power so high after the invention of the steam-powered engine. The age of worldwide European ascendancy that lasted until 1914 and faded away only after 1950 thus depended in important ways on the potato. This was the second and even more important manifestation of the plant's impact on world affairs.

Impact on Populations

Since the Seven Years' war, potato acreage in Europe has expanded in time of war down to and including World War II. Elsewhere in the world, where cool and moist climates allowed them to flourish, potatoes have often played the same role of enlarging food supplies and provoking rapid population growth, though the special advantages Europeans

gained by planting fallow fields to potatoes were seldom equaled. The poverty and vulnerability of Irish potato eaters before the famine of 1845–1847 has also been approached in places like the interior of Papua New Guinea, where agricultural practices are now believed to have developed independently of other cultures (and where domestication of yams, taro and bananas dates to about 7000–6500 BCE). Farming communities in Papua accepted potatoes eagerly, only to suffer disaster when potato blight invaded their fields in 2003.

New Zealand is another place where the arrival of potatoes changed the course of events. The Maori inhabitants of that country depended mostly on sweet potatoes when Europeans first discovered it, although the climate is too cool for sweet potatoes to do well, especially in the south. But *Solanum tuberosum*, introduced in the 1770s by European sailors, thrived, and Maori farmers quickly accepted them. Nourished by potatoes even better than before, they were able to withstand exposure to all the new diseases Europeans subsequently brought with them far better than other newly discovered peoples, and are now a thriving part of society in contemporary New Zealand.

Potatoes remain of little importance in hot climates like those that prevail in Africa, India, and the Muslim lands of western Asia and southern China. In north China they remained a marginal supplement to millet and rice until after 1987, when the government gave up on collective farming and allowed peasant farmers to plant and sell whatever they wished. Potatoes then found a surprising niche in the new China after McDonalds and Kentucky Fried Chicken started selling French fries in 1992 to eager city buyers. To get the uniform quality they required these American firms at first had to import their potatoes, but from the beginning they sought suitable potatoes in China. Two other American companies that specialized in supplying potatoes to American grocery stores set to work teaching Chinese farmers how to best cultivate the new potato crop.

The wind-blown loess soils of the Huang (Yellow) River valley and Inner Mongolia, when suitably

irrigated, turned out to be ideal for raising potatoes. Chinese farmers were apt pupils, once provided with disease-resistant varieties for seed, suitable fertilizers and irrigation equipment. A crop research institute in Yunnan swiftly developed varieties specially attuned to Chinese conditions and made technical advice available to farmers far and wide, so their potatoes soon became as good or better than those produced elsewhere. The area of Chinese potato fields doubled between 1982 and 2002; yields rose by 80 percent, and China became the largest producer of potatoes in the world. They were able to supply McDonalds and Kentucky Fried Chicken with all they needed, and to deliver fresh potatoes to other Chinese buyers while also exporting potatoes to Macao, Taiwan, and even to distant Europe, where their disease-free tubers were valued as seed potatoes and consumed in fancy restaurants whose owners were prepared to pay the extra cost of transportation to get the very best. Potatoes, in short, played a small yet significant part in the startling transformation of Chinese society and economy we have witnessed since the 1980s.

Overall, potatoes in the twenty-first century rank fourth worldwide among food crops—behind rice,

wheat, and maize—no small accomplishment for a tuber once confined to the high Andes.

Printing

Although printing techniques using movable type existed to duplicate writing as early as the eleventh century, Gutenberg's invention of the letterpress in the mid-fifteenth century was the catalyst fostering the widespread dissemination of knowledge and information. In the digital age of cold press (electronic) printing, and with the proliferation of copy machines and computer printers, texts continue to be replicated at an astonishing rate.

Printing is a term with many meanings. It may refer to the stamping of coins or the placing of patterns on textiles. Learning to print may mean shaping letters without using cursive script. This article deals with printing as a process for duplicating writing, and focuses on the developments that ensued after the invention of letterpress printing by the German inventor Johannes Gutenberg (c. 1390–1468) in mid-fifteenth-century Western Europe.

Printing Techniques—East and West

In the context of world history, Gutenberg was a late-comer. The Chinese had been using woodblocks to duplicate writing at least since the seventh century. From the eleventh century on, they were printing some texts using movable types. (After being fixed to a metal plate, the types, made of wood or ceramic, were rubbed by hand on paper.) In thirteenth-century Korea, types made of bronze were developed; later on, a special alphabet was devised to facilitate their use. Despite occasional use of these alternative techniques, printing by means of woodblocks remained the dominant Asian form.

In the West, the replication of hand-drawn images by woodcut and metal engraving is called xylography. It was in use (for making playing cards, among other objects) before Gutenberg's invention. Thereafter it served as a replacement for hand illumination and worked in tandem with letterpress printing (or typography). The latter entailed the use of a wooden handpress, oil-based ink, and types made of lead, tin, and antimony. After the mid-fifteenth century, typography, not xylography, was the dominant method for duplicating texts in the West.

Most distinctive about printing in the West was not so much the new method of duplicating texts but rather the rapidity with which it was adopted in diverse locales and the way the output of printed materials, once underway, was continuously augmented. As is often the case, learning the details about a new technique tells us little about the uses to which it will be put. No doubt the difference between the uneven development of printing in Asia and the continuous exploitation of printing in the West had something to do with the difference between ideographic and alphabetic systems of writing. But many other variables have to be considered.

In some non-Asian societies where alphabets were used, printers were forbidden to apply their craft to sacred texts. In the vast empire governed by the Ottoman Turks, prohibitions against printing not only the Qur'an, but any text in Arabic script remained in effect for hundreds of years (Robinson 1993, 229–251). In Eastern Christendom, religious printing was sanctioned and, indeed, sponsored by the church. Yet in contrast to Western developments, Russian printers started almost a century after Gutenberg and thereafter maintained a very sluggish pace (Marker 1985).

A printed page from one of the British Library's copies of the Gutenberg Bible (c. 1455) reproduces the traditional hand-copied, "illuminated manuscript" style mastered by medieval monks.

Only within Western Europe was the wooden handpress so energetically exploited by so many freewheeling entrepreneurs that some forty thousand editions of books (not to mention edicts, flysheets, broadsides, and the like) had been issued in the first forty years.

The Proliferation of Printing Shops

According to the historian Denys Hay (1967, xxii), printing spread with phenomenal speed; "by the 1490s each of the major states had one important publishing centre and some had several." To understand how this happened, the role of the few major states seems less significant than the role played by many minor ones. Most histories of printing follow the convention of organizing developments around the rise of the major nation-states. (This is notably the case with the multivolumed national book histories that have recently appeared and are still being issued.)

National histories work well enough for nineteenth-century developments, but they distort the geography of the book when applied to the earlier more cosmopolitan age of the handpress. The major centers of book production down through the eighteenth century were *not* congruent with the major political capitals such as Paris, Berlin, Vienna, Rome, Madrid, and London. They were, rather, great commercial centers such as Venice, Antwerp, and Amsterdam. This pattern persisted until the Napoleonic era. "From 1690 to 1790, the works of the most famous French writers were read throughout Europe in editions published outside France" (Febvre and Martin 1976, 196).

Indeed, nation building worked at cross purposes with the rapid expansion of early modern printing industries. The rise of a few large, well-consolidated, dynastic states was less helpful than the presence in late medieval Europe of numerous small political units: bishoprics, communes, free cities, and other assorted quasi-independent states. Right down through the eighteenth century, rulers of small principalities continued to invite printers to set up shop within their realms and thus provide revenues and publicity—that is, to fill town coffers and to satisfy civic pride. The numerous place-names that illustrate the spread of printing across fifteenth-century Europe indicate the eagerness of petty rulers and town councils to get their town's name in print at least once. Many printing offices in small Italian city-states issued only one or two editions before dropping out of the picture. The clustering of printing houses in Venice is reminiscent of Silicon Valley—not least because many of these startups (like recent "dot-coms"), rapidly went bankrupt and closed down (Lowry 1979, 18). The absence of any powerful central authority, whether provided by emperor or pope (in contrast once again to China and Korea or to the Ottoman Empire or Muscovy), provided opportunities for printers, as it did for other merchants and early capitalists, to play one power against another while extending far-flung trade networks from the shelter provided by fortified walled towns.

As the mention of trade networks suggests, when setting the stage for the rapid spread of printing shops, economic developments have to be coupled

with political ones. Late medieval particularism had to be combined with early modern capitalism in order to produce favorable conditions for rapid expansion. The late medieval merchants who were engaged in a wholesale cloth trade had developed extensive networks and sophisticated systems of financing. Textile manufacture was linked to rag-paper production. The output of new paper mills had preceded Gutenberg's invention and had benefited the retail trade in manuscript books. After Gutenberg, book production became a wholesale enterprise. Increased output was spurred by competition among printers and booksellers who curried favor with officials in order to win the privilege of issuing primers, prayer books, edicts, and other works for which there was a steady demand. Problems posed by unregulated competition led to new laws governing copyright, patenting, and intellectual property.

Although the increased output of books was the most dramatic result of the new duplicating process, the profit margin of most early printers hinged largely on their success with "job printing"—that is, with production of nonbook materials such as advertisements, almanacs, calendars, handbills, horoscopes, proclamations, and the like. Of special significance for the subsequent development of science was the increased output of visual aids such as maps, charts, tables, and graphs. Engraved copies of detailed pictures that were especially difficult to reproduce in quantity by hand aided studies in such fields as anatomy, botany, and zoology. Early printers often had instruments as well as books for sale and advertised both on title pages that contained the location of their shops. Although hand copying persisted and indeed thrived after the introduction of printing, it did so within a changed literary environment. Handwriting itself was taught with reference to printed manuals; copyists imitated the title pages, the punctuation, and the pagination of printed books.

Printing and Patrons

Among the cultural and intellectual factors that contributed to the rapid growth of Western printing industries,

Italian humanism is often singled out. Book-hunting literati and their patrons played an important role in recovering and replicating many classical texts that had almost been lost. Thanks to the Greek refugees who worked in the Venetian printing shop of Aldus Manutius (1449–1515), what remained of the corpus of Greek drama was secured from further loss.

The most significant patron of the early printer, however, was the Roman Catholic Church, which had long commanded the largest supply of scribal labor. One of the very first printed products to be issued was an edition of "indulgences." These printed forms, offering purchasers partial forgiveness for their sins, were issued to help raise money for the crusade against the Turks. The printing of anti-Turkish handbills and flysheets also kept job printers busy. The Church also welcomed printing because it offered help with standardizing liturgies and educating young priests. Its patronage is suggested by the location of the first presses in Italy: a monastery in Subiaco and the papal city of Rome. Prohibitions against printing the Qur'an had no counterpart in Western Christendom. Indeed, a future pope admired a copy of the Gutenberg Bible.

The drive to tap new markets encouraged popularization, translations from Latin into the vernaculars, and a general democratization of learning and letters. By the 1500s, these trends were posing new problems for churchmen and statesmen alike. The Roman Catholic Church was divided over whether or not to authorize vernacular translations of Bibles and prayer books. After the Lutheran revolt (1517) decisions were made at the Council of Trent (1546) to authorize only the Latin Vulgate version of the Bible. From then on, lay bible reading was encouraged in Protestant regions and discouraged in regions that remained loyal to Rome. Both Catholics and Protestants used print for proselytizing and propaganda, but only Protestants hailed printing as a providential invention that enabled them to break free of papal rule. Both Catholic and Protestant officials censored the output of printers. But whereas a single *Index of Prohibited Books* provided guidance to all Catholic officials and booksellers, Protestant censorship was

The linotype, a major advance of the nineteenth century in printing equipment, which made setting type easier and quicker.

decentralized, taking various forms in different city-states and princely realms.

In all regions, learning to read paved the way for learning by reading. Autodidacts were urged to master various arts by means of numerous “how-to” texts. Authors, artists, and craftsmen—in collaboration with printers and publishers—used self-portraits, title pages, and paratextual materials to advertise their products and themselves. Individual initiative was rewarded; the drive for fame went into high gear. But the preservative powers of print made it increasingly difficult for successive generations to win notice from posterity. An ever more strenuous effort was required to cope with “the burden of the past” (Bate 1970).

From Scarcity to Abundance

The centuries of hand copying had been characterized by an economy of scarcity. The large collections of texts gathered in the Alexandrian Library and in some later centers of learning were exceptional and relatively short-lived. The retrieval, copying and

recopying of surviving texts took precedence over the production of new ones. The acquisition of literacy was confined to restricted groups of churchmen and lay professionals. Oral interchange predominated. (As noted below, this has led some authorities to contrast print not with handwriting but with speech.)

Printing introduced an economy of abundance. The hand-copied books that continued to be issued for several centuries simply added to a growing supply. The literary diets of Latin-reading professional groups were enriched by access to many more books than had been available before. More abundantly stocked bookshelves increased opportunities to compare previously authoritative classical texts with each other and with more recent work. Academic activities were reoriented from preserving ancient wisdom to registering new findings and venturing into uncharted fields. The expansive character of print culture grew more pronounced during the sixteenth and seventeenth centuries. Multivolumed reference works required constant updating; bibliographies grew thicker and more specialized. Librarians, in particular, were increasingly at a loss as to how to classify and shelve an ever-growing number of books. Merely keeping track of all the new titles became burdensome to bibliographers. Concern about information overload was experienced by each generation in turn.

In the late seventeenth century, the pace of output had increased sufficiently that booksellers began to issue reviews of new works at regular intervals, thus inaugurating the learned periodical press. Even before then, keeping readers informed about financial transactions, sensational crimes, and important battles had become a profitable business conducted by publishers of corantos (broadsides), gazettes, and newsletters. Satires on journalism were familiar to London playgoers who attended Ben Jonson’s *Staple of News* (1623). As the title suggests, news was already regarded as yet another commodity to be bought and sold.

Communications: Print versus Voice

The constant increase in books and other reading matter represents the diachronic aspects of print

culture. There were also synchronic aspects. Unlike hand-copied works, printed copies were issued not consecutively but simultaneously. The receipt of the same work by diverse readers within the same interval encouraged better coordination of diverse activities. The output of the handpress fell short of achieving the degree of standardization that marks modern editions. Yet early modern readers were able to argue, in both scholarly tomes and polemical pamphlets, about identical passages on identically numbered pages. The distribution of printed copies was relatively slow before the development of modern transport systems. Nevertheless, the age of the wooden handpress saw a marked improvement in the capacity of scattered observers to check the path of a comet against diverse predictions and to send in new findings and corrections to the editors of atlases and other reference works. Coordination took on political significance when opponents of a given regime were able to distribute pamphlets and mobilize protests in different parts of a given realm. “We made the thirteen clocks strike as one,” commented the U.S. revolutionary Benjamin Franklin.

With the output of pamphlets, journals, and newspapers, the conduct of political affairs became more difficult to contain within traditional structures. Merely by contributing letters to the editor, ordinary citizens were newly empowered to participate in public debates. Writers, who were offended by a miscarriage of justice, increasingly began to appeal over the heads of duly constituted authorities to a reading public at large. In 1775, Malesherbes (the director of the French book trade) observed, “in an enlightened century . . . each citizen can speak to the entire nation by way of print . . . men of letters are, in the midst of a dispersed public, what the orators of Greece and Rome had been in the midst of a people assembled” (Malesherbes 1989, 92).

The transmission of messages via print rather than voice points to a facet of print culture that provoked much debate. It centered on the contrast between reading and hearing. To the French Enlightenment *philosophes*, impressed by advances in the mathematical sciences, the use of print held the promise of

introducing rationality into political affairs. Whereas speech was ephemeral, they argued, a printed account lent itself to rereading and careful consideration. By means of rhetorical devices, orators could persuade their audiences to perform ill-considered acts. Legislators were less likely to be “carried away” by a treatise than by a speaker and were more likely to think calmly and carefully before taking action.

The same “distancing” effect of print that the French *philosophes* viewed as beneficial, others found objectionable. The Romantic movement of the early nineteenth century entailed a reaction against the sort of abstract thinking that had characterized revolutionary efforts to redesign the complex social structures of France under the old regime (the period before the 1789 Revolution) in accordance with a single blueprint. Political romanticism took the form of lamenting the way “the age of chivalry” had succumbed to that of “economists and calculators” (Burke 1790). Oral traditions, supposedly uncontaminated by print, were valued for preserving the true spirit of a given “folk” or people. Readers were urged by Romantic poets such as Wordsworth to abandon book learning: “close up those barren leaves!” Objections to the purported distancing effects of print persisted among critics and media analysts in the twentieth century. “Through the habit of using print and paper,” wrote Lewis Mumford (1934, 136–137) “thought lost something of its flowing organic character and became abstract, categorical, stereotyped, content with purely verbal formulations and solutions.” Marshall McLuhan (1962, 36–37) took a similar position by in his depiction of “Typographic Man.”

Both the proponents and opponents of the ostensibly impersonal, abstract character of print tended to overlook its coexistence with a human presence and a human voice. One thinks immediately of parents reading to children. But any text that appears in print lends itself to being read aloud. During the early modern era, printed broadsides and news reports were especially likely to have been transmitted by word of mouth to listeners gathered around a few literate townsmen. Even now, public readings or lectures are delivered to hearing publics by the authors

of printed bestsellers. (During recent decades, of course, print and voice have come together in the form of “audiobooks.”)

Print culture did not supersede oral culture but did have an effect upon it. Printed ballads decorated the walls of rural cottages. As was true of handwriting, the speech arts, far from languishing, flourished in a more regulated form. Instruction in elocution and in holding debates figured among the many “how-to” books that printers kept in stock. There were exceptional preachers (such as the Marian exiles or the Huguenot refugees) who, when deprived of their pulpits and sent into exile, turned to printing as their only recourse. But most preachers (like Savonarola and Luther) made full use of both pulpit and press.

Other considerations cast doubt on the “distancing effect” of print. Whatever the effects of printed cartoons and caricatures, they cannot be described as distancing. Similarly the figure of a distant ruler became less distant when printed (or photographed) portraits could be cut out of newspapers and enshrined in peasant huts (as was done in Czarist Russia.) Even with regard to “bare” texts, a skillful writer (whether distant or dead) could (and still can) move unknown readers “to tears” or incite them to take action. The presumably “impersonal” quality of newsprint, not the rabble-rousing on the soapbox, got credit for generating hysteria and war fever by American opponents of the Spanish–American War (1898) and British opponents of the Second Boer War (1899–1902).

Industrialization and Digitization

The basic features of Western print culture remained more or less the same after the industrialization of paper-making and printing processes in the early nineteenth century. Subsequent technological innovations, which led to the eventual replacement of “hot type” (set type) by cold (computerized offset printing) in the twentieth century only helped to increase output and to exacerbate concern about overload.

The most noteworthy nineteenth-century development was the increasingly important role played by

the newspaper press. The two key dates are 1814, when the London *Times* was turned off an iron rotary press powered by steam, and 1836, when Emile Girardin inaugurated *La Presse*. (This paper doubled its circulation and halved its costs, compared to previous Paris newspapers, and gave the French term “La presse” its special journalistic significance.)

Especially after the advent of wire services that made use of the telegraph, the daily delivery of newspapers would restructure the way readers experienced the flow of time. According to the scholar Benedict Anderson (1999), the reception of the same news at more or less the same time every day gave rise to a sense of collective participation in an unfolding national narrative that had no counterpart in earlier times.

By the 1830s, the British newspaper press was already being described as a “fourth estate” of the realm and was being assigned great influence over the public mind. Such an idea appealed to press barons and editors. “Books have had their day. Theatres have had their day. Religion has had its day. Nothing prevents the newspaper from being made the greatest organ of social life,” announced the U.S. publisher James Gordon Bennett in 1835 (Mott 1940, 232–233). What pleased newspaper editors was a matter of concern to others who worried that the popularity of the newspaper came at the expense of less ephemeral reading matter. The British philosopher, economist and moral theorist, John Stuart Mill (1806–1873) was concerned that people were no longer taking their opinions from books. “Their thinking is done for them by men much like themselves through the newspapers” (*On Liberty*, 1859, 66). After the century’s end, the historian Oswald Spengler would assert that “the newspaper had completely expelled the book from the mental life of the people.” As had Thomas Carlyle and Louis Blanc, Spengler believed that the age of the book had ended. It was “flanked on either hand by that of the sermon and that of the newspaper” (Spengler 1928, II, 461, 463).

In twentieth-century America, however, the age of the sermon was given a new lease on life thanks to the

Press at the Richmond & Backus Company (now the Detroit Publishing Company), Detroit, Michigan, circa 1902.

advent of the so-called electronic church. Electronic media, such as radio, film, and television, represented what the historian Walter Ong (1971, 285, 296) called a “secondary orality.” Despite expectations that the new media would drive out the old, the so-called paperback revolution of the 1950s and 1960s led to increased book sales. Moreover, filmed and televised versions of popular novels by Charles Dickens, Jane Austen, and others, far from outmoding printed copies, spurred the issue of new editions. So did celebrity recommendations on television.

With the advent of the digital era, the movement of texts onto screens has persuaded many observers that the end is finally at hand. Enthusiasts dismiss “dead-tree editions” as hopelessly out of date, and book-lovers write elegies to Gutenberg (Birkerts 1994). Oddly enough, in view of nineteenth-century predictions, the book seems to be less endangered by online publication than is the newspaper. The machinery and transport systems required to get daily newspapers into print and at the doorsteps of subscribers are costly and cumbersome compared to the swift and easy delivery of texts onto screens. But although online publication does pose a threat to many daily papers and is already reducing advertising revenues, it continues to facilitate the browsing and the purchasing of printed books.

The virtual bookstores that display titles on screens do so not to encourage further recourse to computers but rather to facilitate the sales of real books shelved

in brick-and-mortar structures. Furthermore, thanks to the photocopiers that are placed in libraries and shops, and the printers that accompany most home computers, texts are being replicated at a rate that defies calculation. The output of the printed word in this new age of cold type and mixed media has at least one thing in common with the output of the wooden handpress. Not a scarcity of texts but an overabundance still seems to be a chief cause for concern.

Progress

Progress (Latin: *progressus*) originally meant moving across country to a chosen destination. Progress toward individual betterment was a derivative meaning that entered English with John Bunyan's *Pilgrim's Progress* (1678). The idea that society as a whole might progress was slower to emerge, taking shape during the Industrial Revolution. Technological "progress" has, of course, exhibited destructive capabilities that prompt the question: change is everywhere, but is it really for the better?

Ever since 1492, when Europeans first began to sail across the oceans, advances of geographical and mathematical knowledge accumulated rapidly. Scientific progress became obvious by 1687, when Isaac Newton published mathematically formulated laws of motion, making eclipses as well as more ordinary movements of sun, moon, planets—and even cannonballs—predictable. Writers like the French scientist, Bernard de Fontenelle (1657–1757) concluded that progress of knowledge was real and might be expected to continue indefinitely into the future, but unchanging laws of nature meant that human society as a whole would remain much as before.

As long as most people lived just about the same way their parents and grandparents had done, any other opinion would have seemed absurd. But beginning about 1750 a cluster of changes began in Great Britain and western Europe that historians later called the Industrial Revolution. The central feature of that revolution was expanding the output of useful goods by using inanimate forms of power—first falling water, then coal and steam, and then electricity—to

drive large, often complicated machines. As a flood of useful things began to come from such machines, human lives in western Europe began to change unmistakably, and sometimes for the better, as cheaper manufactured goods became available.

Engines of Change

But at first the biggest improvement for most people was not industrial at all. Rather, food supplies increased enormously in Europe due to the rapid spread of potato cultivation after 1763, when all the principal governments of the continent set out to imitate the Prussians who, fifteen years before, had pioneered official efforts to persuade peasants to plant their fallow fields with potatoes. Potatoes meant more work, since they had to be hoed in summer to remove weeds. But as long as enough hands could be found for that task, potatoes multiplied the amount of food European fields could produce without diminishing the grain harvest in the slightest. This, together with use of turnips and other fodder crops as a parallel alternative to fallowing, radically diminished age-old risks of famine and provoked two centuries of population growth for humans and for their domesticated animals. That in turn assured a supply of people, horses and cattle for intensified cultivation in the European countryside, and soon provoked a surge of migrants looking for wage work in burgeoning industrial towns.

Economic expansion thus became self-sustaining; and as new styles of farming and new forms of industry spread, the daily experience of almost everyone in western Europe began to change in obvious ways. These novelties soon began to affect the entire world

This Maoist Chinese proverb says, "Greater, faster, better, more economical."

as well. Not all changes were for the better. Living conditions in crowded industrial cities were often horrible, and alternating patterns of boom and bust meant insecurity for all and inflicted severe suffering on unemployed wage earners. But new possibilities and cheaper goods were just as real. Think, for example, of what it meant for ordinary persons—especially those with small babies to swaddle and keep more or less clean—when, as the utopian socialist Robert Owen tells us in his autobiography (*The Life of Robert Owen Written by Himself*, 1920), in 1858 the cost of cotton cloth in England had shrunk to one seventieth of what it had been sixty years before when he started work as a teenager. During that same life span, steam railways, introduced in 1825, drastically cheapened and speeded up overland transport for goods and people; and after 1837 electric telegraphs allowed instant communication, at first only for a few, later for nearly anyone with an urgent message to send.

As significant novelties multiplied, it became obvious that human lives and the whole structure of society was changing as never before. Ever since a cascade of new technologies, new products and new experiences has continued, and even accelerated, spreading from an initial focus in Great Britain and adjacent parts of Europe quite literally around the Earth.

As always, new possibilities brought new risks and damaged or destroyed old ways of life. Most of the time, most people welcomed enlarged possibilities and liked to have access to cheaper machine-made goods. Yet costs were real too. Everywhere artisans found they could not compete with machine-made products; and old-fashioned agrarian empires found that they had to allow European goods, merchants,

missionaries and soldiers to intrude on their territories more or less at will. The flood of new products soon affected even the most remote hunters and foragers whose ways of life were upset by encounters with such items as iron tools and, not least, handguns.

But looked at from the center of disturbance, the rapid growth of wealth, population and political power that Britain, France, Germany, and the United States all experienced between 1800 and 1914 seemed a thoroughly good thing to almost everyone. Accordingly, the idea that human society was destined to progress in desirable directions soon took hold among these peoples. An early champion of that idea was a French nobleman, the Marquis de Condorcet (1743–1794), who wrote *Sketch for an Historical Picture of the Progress of the Human Mind* in the year of his death. His confidence in human progress toward perfection remains surprising, considering the fact that he was in prison and about to have his head cut off by the French revolutionary government when he wrote his sketch.

In the next century, as desirable novelties multiplied, the idea of progress took firm hold among Europeans. In Germany, the philosopher Georg Wilhelm Friedrich Hegel (1770–1831) made progress a universal principle of reality, moving from thesis to antithesis and then to synthesis, which immediately became a new thesis to keep the process going. Karl Marx (1818–1883) claimed to have stood Hegel on his head by proving that class struggle toward equality and freedom under Communism was the path of the future. Before that, in France another nobleman, Count Henri de Saint Simon (1760–1825), founded a different socialist movement aimed at hastening progress towards a similarly free and equal future. One of his younger associates, Auguste Comte (1798–1857), founded what became the academic discipline of sociology with parallel aims. Meanwhile in England the philosopher and economist, John Stuart Mill (1806–1873), and the historian Henry Thomas Buckle (1821–1862) explored a more open-ended liberal version of progress in their articles and books.

Skyscrapers spring up in Tianjin, China—a sure sign of progress for this former port city, many in China believe, where reminders of foreign occupation during the Second Opium War (1856–1860) and after are still evident in the architecture of churches and villas built in that era. Philip Baguet Collection.

In 1851, the reality of material progress was spectacularly demonstrated when Prince Albert, Queen Victoria's husband, organized a very successful Great Exhibition in the Crystal Palace, London. Beneath a specially constructed iron and glass structure, exhibitors from far and wide displayed a vast array of new machines and products for public admiration and instruction. Thereafter, similar world's fairs became quadrennial events, achieving a new peak of success in 1893, when Chicago hosted the World's Columbian Exposition. That fair celebrated four hundred years of progress since Columbus's discovery of America, and met with altogether unusual success. A still new trans-continental railroad net made it possible for more than twenty-one million persons to attend the fair; and at night, when incandescent electric bulbs lit up plaster-covered temporary buildings, the dazzling

whiteness seemed like a preview of heaven to many of the fair's visitors. Progress never seemed so certain and so obvious, before or since.

The success of the Columbian Exposition depended partly, too, on the fact that the idea of progress had enlarged its scope and persuasiveness after 1867, when Charles Darwin published *The Origin of Species*. Darwin argued that plants and animals had evolved through geological time thanks to a process of natural selection; and in another book, *The Descent of Man* (1871), he specifically discussed human evolution from ape-like ancestors. This challenged the biblical story of creation head on and provoked intense and prolonged controversy. Accordingly, one of the innovative features of the Columbian Exposition was a World Parliament of Religions where spokesmen for each of the world's principal faiths had a chance to come before an American public,

Life can only be understood backwards; but it must be lived forwards. • Søren Kierkegaard (1813–1855)

looking for shared principles and in some instances, even exploring the plausibility of religious progress through time.

There had always been doubters who discounted the desirability of all the tumultuous changes that beset nineteenth-century societies; and in the course of the twentieth century, doubts about human progress multiplied. The long stalemate of trench warfare in World War I (1914–1918) made the military side of technological progress, of which their nineteenth-century predecessors had been so proud, seem anything but desirable to millions of European and American soldiers; and the postwar boom, followed by the Great Depression (1929–1938) and World War II (1939–1945) broadened and deepened that skepticism. Renewed economic growth after 1950 was counterbalanced by fears of sudden atomic annihilation and by uneasy awareness that rapid population growth in Africa and Asia was widening the gap between the rich and poor peoples of the Earth.

By the beginning of the twenty-first century, though nearly all the world's politicians still promised to accomplish all sorts of good things if elected to office, most writers and commentators on public affairs took a much gloomier view of the future. Emphatic rejection of the nineteenth-century faith in progress became general. That was partly because continuing improvements in human comfort and diet as experienced by people in the world's wealthiest countries, like air conditioning in summer, and fresh fruit and vegetables in supermarkets all year round, swiftly came to be taken for granted, while innumerable medical breakthroughs, like antibiotics and heart surgery, had the immediate effect of prolonging life and thereby multiplying the pains and debilities of old age.

Destructive capabilities of biological, chemical, and nuclear weapons also multiplied; while gaps between rich and poor, rivalries among ethnic and religious groups, and the decay of local communities seemed only to increase. All too obviously, change was everywhere, but was it really for the better? Did happiness increase with longer life and more things to own and look after? Or did accumulating material goods merely get in the way of leading a good life?

These are valid reproaches against rosy nineteenth-century predictions of moral and political progress. But material progress remains undeniable. No one can doubt that increasing knowledge and skills have enlarged human command of energy flows at a very rapid rate since 1750, and have done so more slowly throughout history. The resulting increase in human capabilities, both for good and for ill, is clearly cumulative, and constitutes a kind of progress that deserves to be recognized as such.

Protestantism

Protestantism, which thrives in numerous denominations and usually adapts to the cultures of the congregants to whom it has spread since the sixteenth century, uses the Bible as its authority and stresses the grace of God. Religious demographers estimate the number of Protestant Christians worldwide to increase from 370 million in the early twenty-first century to half a billion by 2025.

Protestantism represents a form of Christianity that spread in five hundred years from northwest Europe to every continent. This global version of the faith derives from a cluster of movements within Western or Catholic Christianity in the early sixteenth century and thrives in the form of thousands of independent church bodies. Rejecting the authority of the pope, Protestants almost universally profess that the Bible—that is, the Hebrew Scriptures and the New Testament—is the authoritative source and norm of their teaching. Through the centuries, Protestantism quite naturally took on the culture of whatever new environments its churches spread to. Thus Lutherans in Namibia differ in many respects from those in Norway, yet both stress the grace of God and are critical of any teaching that they associate with the historic Catholic teaching that insisted on human endeavors to impress and please God.

Global Protestantism Today

Early in the twenty-first century, religious demographers estimate that about 370 million people are Protestant. Often associated with Protestantism but insisting on its Catholic character is Anglicanism, the heritage of

the Church of England, which numbers 82 million adherents; a third group, informally labeled Independents, numbers 415 million. Taken together, after 2000 these non-Roman Catholic varieties of Christianity, all of which derived from the sixteenth-century Reformation, have over 800 million followers. (By comparison, there are an estimated 101 million Roman Catholics and 217 million Eastern Orthodox adherents.) Demographers estimate that by 2025 the Protestant numbers will grow from 370 million to almost half a billion, a sign that Protestantism is not confined to the period of early prosperity from the sixteenth through the nineteenth century, but faces a prosperous yet at the same time an ambiguous future. While these are necessarily imprecise numbers, the totals suggest the enormous historical importance of this movement.

The momentum of Protestantism, however, has dramatically shifted. While much of its base remains in northwest Europe, the point of its origin, the membership there is often nominal. In some Scandinavian nations, for instance, over 90 percent of the population will be listed as Protestant because most children are baptized by the Lutherans, yet church participation is very low. Meanwhile, in sub-Saharan Africa, where several thousand new members are added every twenty-four hours, Protestants, especially in forms called “Pentecostal” or “charismatic,” as they expand, are known for their vital and even exuberant patterns of worship and are among the chief deliverers of health care and works of mercy.

Protestant Origins in Western Europe

While Protestantism did not receive its name until 1529, historians of Protestantism characteristically

date its rise from sporadic pioneering reform movements in England under John Wycliffe (1320–1384), William Tyndale (1494?–1536), and others. They and their followers combined efforts to translate the Bible into English and then to use biblical teachings, as they interpreted them, to criticize the Catholic Church. The Czech reformer Jan Hus (1372–1415), a critic of Catholic practices who died for his faith, endeavored to break the hold of the hierarchy and to teach lay people to base their views of divine grace on the Bible.

While the English reformers and the Hussites were put out of the Catholic Church or put to death, many other reform movements which tested the Roman church of the day, denouncing it as legalistic, corrupt, and inefficient as a deliverer of the message of divine grace, remained within the Church. Typical among this group were humanists like Desiderius Erasmus (1467?–1536) of the Netherlands, a man who satirized the papacy and monasticism with a wit and savagery unmatched by most of his Protestant-leaning contemporaries. However, Erasmus and other humanists in the universities of England and throughout the Holy Roman Empire on the continent could not envision carrying their reform to the point of a break with the papacy.

Breaks that led to permanent breaches began to occur in the second decade of the sixteenth century. Most visible and best-remembered among them were the university-based reforms at Wittenberg in Saxony. A cluster of monks and professors led by Martin Luther (1483–1546) set out to attack the Church's modes of dealing with people who sought salvation and attempted to live a moral life. Luther and his followers saw the Papacy as repressive, self-centered, and corrupt, and declared their intent to recast Church teachings from within Catholicism. However, they became so upsetting to both the Church and the Holy Roman Empire that Rome took action—usually, as in the case of Luther, it excommunicated them as heretics. Many other critics left voluntarily.

The map of early Protestantism indicates that a great number and variety of sites developed quickly. In England, a controversy between the Pope and King Henry VIII led to a sundering of ties and the birth of the Anglican Church. In Switzerland, reformers such as Huldreich Zwingli (1484–1531) and John Calvin (1509–1564) complemented or competed with Luther and the Germans and with Scandinavian leaders, while more radical reformers spread through Switzerland and the Lowlands. By mid-century essential changes in allegiances had occurred and Protestantism had reached its early geographical limits. However, Mediterranean Catholics on the Iberian Peninsula, in France, and in the Italian states were unmoved, as were Eastern Europeans, whose Catholic churches abutted Orthodox churches in Russia, Poland, and Greece.

The Inner and Outer Expressions

The early Protestants, who acquired their name almost accidentally from the act of some princes who “protested” imperial and Catholic action at the Diet of Speyer in 1529, were more frequently referred to with a more congenial and positive term, *evangelical*. Although five centuries later that name appears to characterize only conservative Protestantism, in the beginning it simply implied that those who professed it were devoted to the *evangel*, the message of the New Testament gospels. They were not to be confined by Roman Catholic Church law and did not define themselves as legalistic followers of Jesus and the church. Instead, they professed to take the risk of governing the church and inspiring individual members' lives with the message of grace as mediated only by the Christian gospels and voiced in the acts of preaching and prayer.

The inner expression of Protestantism arose from the way some Christians gave expression to this evangel, how they worshiped and lived. The outer expression refers to the ways in which Protestants in various societies and cultures

related to governments and economic and social powers.

The Gospel and the Inner Life of Protestants

Once the hold of the papacy and the Catholic hierarchy was tested and broken, the people called Protestant set to work to give voice and form to personal and church life in ways that would distance them from Rome and yet keep them within the Christian tradition, a tradition that they were soon to claim as belonging more rightfully to them than to the members of what they considered a corrupt Catholic church. Many Protestant leaders, especially the Anglicans and the Lutherans, continued to think of themselves as representing a kind of Catholicism without a pope, and they affirmed all that they could from the life of the existing Church. Yet their criticism of its forms was often searching, radical, and even savage. In fact, for many, the pope became not a faulty follower of Christ but the Antichrist.

Although they were unwilling to be defined only negatively vis-à-vis the Roman hierarchy and church or canon law, Protestants had difficulty defining themselves positively. The genus had to include everyone from Anabaptists, ancestors to latter-day Mennonites

and radical Baptists, to church bodies that worshiped in very formal ways, including the use of incense and what radicals considered reintroducing the trappings that belonged in Rome, not in evangelicalism. The genus also had to include Protestants who supported the religious establishment, who did not sever the ties between religion and regime, separate “church and state,” or cease taxing the whole citizenry for church support. At the same time, in the same cluster, were Protestants—again, the Anabaptists and Baptists led the way—who wanted religious life in their churches to be independent of political organizations and leadership; they advocated very simple forms of worship that demonstrated their distance from Rome.

Authority and Grace

Despite these diversities and the outlooks and actions of many charismatic reformers who started independent movements, some broadly defined motifs can be used to characterize most Protestants. First, most of them did and still do give highest priority to the canonical scriptures, which they share with Catholics. Most Protestants, however, want to downgrade Catholic affirmations of church tradition and papal interpretations of the Bible. They may affirm that the Christian faith had been expressed through the ages

wherever Catholics were baptized or where they observed the Lord's Supper ("the Mass") as a second sacrament, where the gospel of Jesus Christ was read, and where it served as the basis of preaching and teaching to summon people to faith and the living of a godly life. The Protestant rejection of so much tradition and its refusal to turn to other authority, led Protestants to put a major, sometimes unique, stress on divine revelation in Scripture (on the interpretation of which the various groups disagreed with each other). One frequent statement of this motif was the authority of *sola scriptura* (scripture alone).

Second, while Protestants differed from each other in interpreting the scripture, most found in the writings of Paul and classic teachers such as Augustine an accent on divine grace. In this case, the distinctive elements were *sola gratia* (grace alone) and *sola fide* (faith alone)—people were saved from sin and from eternal punishment by the graceful and generous action of God, especially through the death and resurrection of Jesus Christ, in whom they had faith. Catholics, of course, also acknowledged divine initiatives, but in the eyes of Protestants their emphasis on the need to please God through personal merit or works made them subject to Rome, which stipulated exactly how they should acquire merits and which works were beneficial to those who would be saved.

Continuing to baptize and to celebrate the Lord's Supper or Holy Communion, the sacred meal that memorialized Jesus and, most said, was a means of imparting grace among believers, the majority of evangelical Protestants simplified worship. Preaching, singing hymns, and saying prayers became the main features.

Authority and Public Life

Protestants, whose early breakthroughs were often connected with particular nationalist or territorial movements and strivings by political rulers, knew that they had to find ways to promote civil life and instill obedience among populations. Few were ready to go so far as to repudiate existing earthly authority, be it that of emperors, monarchs, princes, or

magistrates. Indeed, many of the latter converted to Protestantism and gave protective cover to reformers who were allied with them and who promoted their cause. By 1555 at the Peace of Augsburg, all but the radical reformist Protestant leaders had signed on to a concept that they took for granted: *cuius regio, eius religio* (whoever determined the government of a region stipulated what religion should be favored or have a monopoly).

That halfway stage of reform led many Protestant leaders to adopt a servile attitude to their government, and many clergy became lower-grade civil servants. Dependent upon the government for funds, they were often uncritical of rulers, and Protestant radicals charged that they were replacing the tyranny of the pope with the tyranny of princes. Yet from the beginning, early Protestant witnesses to the value of conscience and of relative autonomy in respect to spiritual choices produced a widespread restlessness that by the middle of the seventeenth century had led to edicts and settlements of toleration in England and elsewhere.

A century later, these protesting impulses and liberated consciences served many Protestants as they teamed up with political thinkers, revolutionaries, and statesmen, to draw a line of distinction between the sphere of religion and the civil authorities—to use the terms of American constitutionalist James Madison—or the separation of church and state, Thomas Jefferson's term. Such distinguishing and separation became marks of Protestant life in the United States after 1787, and were important instruments in determining Protestant church life when its missionaries founded churches in Asia and Africa, where no form of Christianity became more than a small minority presence.

Not all the external life of Protestant Christians had to do with government and politics. There was also an accent on personal ethics, based on the gospel in ideal circumstances, though many evangelical churches developed laws and nurtured legalistic ethics. As religion and regimes became more independent of each other, the ethic of "faith made active in love" inspired Protestants during and after the

eighteenth century to invent many forms of voluntary associational life. Their churches formed groups where leaders and followers could promote charity and reform. The legacy of these inventions in the late eighteenth century, especially in Anglo-America, is evident wherever the Protestants took their efforts to convert people, even on continents where Protestants were never more than a minority presence.

Protestant Phases of Development

The first generations of Protestantism were what sociologist Emile Durkheim called “effervescences,” bubblings-up, hard-to-discipline eruptions, usually marked by the language and life of an outstanding leader. By the second generation such movements, in order to sustain themselves and give an accounting of their ways, saw the rise of definers. Thus in the Church of England, Richard Hooker (1554–1600) brought legal expertise to the drafting of the *Laws of Ecclesiastical Polity*. John Calvin, arriving on the scene slightly later on the scene of reform than Luther or Zwingli, was himself a principled systematic theologian and defined the Calvinist or Reformed wing of Protestantism with his *Institutes of the Christian Religion*. Martin Luther, a man of contradictions who favored paradoxical language, gave place to university systematicians in the seventeenth century, giants of dogmatic expression like Johann Gerhard. The impulse among the second-generation leaders was to reintroduce more legalistic norms and in some cases to adopt the scholastic approach to faith which their predecessors had criticized. This meant that they offered philosophical defenses of the verbal inspiration of the Bible or reasoned apologies for the existence of God and the workings of grace.

Such defining legalism and scholasticism, especially where Protestants were linked with and dependent upon civil authorities, could follow a predictable means toward an unsurprising end. That is, they often appeared to degenerate into desiccated or fossilized forms, inert, incapable of keeping the evangelical spark alive. Such kinds of settlement bred restlessness. Thus, in a third long generation or short century of

Protestant life, inspired leaders and movements from within devoted themselves anew to the inner life of the individual prayerful soul, the piety of believers, and the reform of worship. These eighteenth and early nineteenth century movements, concurrently in the *reveil* in French-speaking lands, the *Glaubenserweckung* among German speakers, and the “awakening,” “revivalist” or “pietist” movements in the British Isles and the American colonies or young United States, brought forth fresh accents.

Now the concentration was on the personal experience of God acting through the Holy Spirit to lead individuals from indifference or apathy to fervent faith. The converts, once “awakened” or “revived,” were to turn to their reprobate or spiritually lifeless and wicked neighbors and convert them. Then they were to form small groups, often within the established church, as was the case with Jonathan Edwards or George Whitefield, the towering figures in colonial America at mid-century, or with John Wesley, who eventually moved out of the Church of England to form Methodism. In general, these awakened movements matched and fed the democratic spirit of the times and empowered lay people to engage in works of reform and missionary endeavor.

In the nineteenth century, the age of colonialism, such awakened Protestants, moved by the sense that they were advancing the millennium (for Christ’s return to Earth) or promoting human progress through conversion and reform, boarded ships from the British Isles, western European nations, and the United States, and took their gospel to the Middle East, Asia, and the Pacific Island world, sometimes but with less success in Catholic Latin America, and finally to Africa. Most of these evangelical missionary movements date from the 1790s in England and after the 1810s in the United States.

Gifted college graduates, ambitious entrepreneurs, and sacrifice-minded men and women accompanied their message of salvation with efforts to educate and then provide physical benefits for the populations they reached. It is easy to connect their moves with colonial and imperial impulses, but without the entrepreneurs and conquerors they could probably

Wherever the battle rages, there the loyalty of the soldier is proved and to be steady on all the battlefield besides is mere flight and disgrace if he flinches at that one point. • **Martin Luther (1483–1546)**

not have moved as efficiently as they did. Yet they paid a high price, because anti-colonialism eventually made it necessary for them to distance themselves from many of the Euro-American missionary endeavors—in sub-Saharan Africa, for example. They developed what they thought of as autochthonous Protestant churches—that is, churches rooted in the cultural soil of their new country.

At the beginning of the twentieth century, a new expression of Protestantism called Pentecostalism broke forth. Pentecostals claimed that their charismatic form of Christianity was as old as the biblical prophets and the New Testament. They believed they were reviving gifts of early Christianity, which had long fallen into disuse. They “spoke in tongues,” for example; they prophesied and claimed miraculous healings. Pentecostalism quickly became a dominant form among Protestant late-arrivals in Latin America and sub-Saharan Africa. Some demographers claimed that over 570 million Protestants, Anglicans, Independents, and sometimes even Roman Catholics were Pentecostal. Having become the dominant form in the emerging world, Pentecostalism seemed ready to become the most prominent form of global Protestantism as the European churches declined in numbers and significance.

One Millennium Ends, Another Begins

Through centuries, Protestantism developed many schools of theology, not least impressively in the twentieth century, long after many cultural observers had expected such fresh flowerings in a secular world. These schools reflected the dominant philosophies of the day, as their ancestral versions had done during periods characterized, for example, by idealism and the Enlightenment. In the same way existentialism, language analysis, phenomenology, and other philosophies inspired Protestant thinkers, usually in university settings, to rework biblical and historic evangelical motifs to meet new challenges. These included coming to terms with whatever industrialization, urbanism, globalization, and humanistic

crises brought to people’s lives. Far from fading, as it seemed to be doing in its own heartland, Protestantism in the early twenty-first century represents a confusing, explosive, adaptive force in secular and religiously pluralistic settings. Hard-line reactive Protestant fundamentalists resist adaptations, but their leaders manifest an ability to engage in invention on the ever-changing front of Protestantism.

Qin Shi Huangdi

(c. 259–210 BCE)

CHINESE EMPEROR AND FOUNDER OF THE QIN DYNASTY

Qin Shi Huangdi, founder of the short-lived Qin dynasty (221–206 BCE), unified China after years of internal strife and warfare. Although he was a tyrannical leader, he established standards of currency, weights, measures, and even the width of roads and cart axels. Under his rule the written script was purged of regional variations, easing communications and reinforcing cultural unity, at least for the literate elite.

The unifier of China after several centuries of internecine warfare, Qin Shi Huangdi established the principle of centralized rule, with court-appointed officials governing throughout his realm. But his dynasty, for which he created the new title “Huangdi” (literally, First Supreme Sovereign), or emperor, barely outlived its founder, collapsing under the onslaught of popular rebellions just four years after his death.

In traditional Chinese historiography, Qin Shi Huangdi was remembered as an extreme tyrant whose cruelty and megalomania caused the rapid collapse of the dynasty for which he had designated himself founding (shi) emperor in what was to be an unending line of descent. The popular suffering accompanying the forcible unification of China was probably real enough, but the adoption of Confucianism by the succeeding Han dynasty (206 BCE–220 CE) as the official state philosophy probably was responsible for Qin Shi Huangdi’s becoming a lasting symbol of oppression. Late in his reign Qin Shi Huangdi had tried to eradicate dissenting opinions by banning all traditions and schools of thought except the Legalist teachings that had been adopted by his home state of Qin a century earlier. This proscription hit Confucian

scholars hardest, and it was for his great crime of allegedly burning the books and burying the scholars (alive, of course) that the First Emperor was chiefly remembered in later China’s Confucianized historical memory.

With the rise of modern Chinese nationalism, Qin Shi Huangdi has acquired a more positive image as a political unifier and nation builder. Mao Zedong (1893–1976) went further, seeing him as the kind of great leader who pushed the wheel of history forward by ruthlessly exterminating traditional or reactionary forces. In Mao’s last years, during the later stages of the Cultural Revolution (1966–1976), there was a nationwide campaign to glorify Qin Shi Huangdi as historically progressive and to denigrate Confucius as reactionary. That campaign ended, however, with the death of Mao. Qin Shi Huangdi remains a rather ambiguous symbol in modern China, seen on the one hand as a great national unifier and on the other as a tyrant and despot.

Appraising his real achievements is not easy. Significantly, critics and admirers in China focus more on his role as a political centralizer than as a military conqueror, although his armies crushed all the remaining independent Chinese states and pushed China’s boundaries to present-day Vietnam in the south and beyond the present Great Wall (which his laborers began to build by connecting and extending existing fortifications) in the north. Important in his role as a centralizer was the junxian system with which he administered his vast empire. Formerly hereditary fiefdoms held by not-always-obedient retainers were replaced by commanderies and districts administered by officials serving at the emperor’s pleasure. While execrating his name and policies,

The soldiers of Qin Shi Huangdi's terracotta army had hollow torsos, solid legs for stability, and molded heads with hand-carved, distinctive facial features to reflect the multicultural backgrounds of the emperor's troops. Photo by Yixuan Shuke.

the Han dynasty that followed basically accepted this system, which became the norm for later Chinese imperial government.

The Han also continued many of Qin Shi Huangdi's other unification policies, such as standardization of currency, weights, measures, and even the width of roads and cart axels. In cultural matters, the Qin suppression of various philosophies and traditions was dropped, although the Han's designation of Confucianism as the state orthodoxy also dampened the vigorous philosophical disputations that had characterized the latter years of the pre-Qin Zhou period (1045–256 BCE). One other Qin standardization was of enormous historical significance: the written script was purged of regional variations, thus facilitating communications and reinforcing cultural unity, at least for the literate elite.

The most notable discontinuity from Qin to Han was the repudiation of the School of Law (*fajia*) that Qin Shi Huangdi had made the sole philosophy, or political doctrine, of his empire. Usually called Legalism in the West, the School of Law demanded universal law codes, enforced by harsh punishments, which would abolish all the old feudal distinctions

of rank and privilege, thus leveling society under the all-powerful ruler. As explained by its most articulate spokesman, the political philosopher Han Feizi (d. 233 BCE), this would not only maximize power for the state and the ruler, but also benefit the common people by ensuring peace and good order. There was little attention paid to law as a restraint on the absolute power of the ruler.

Upon the death of Qin Shi Huangdi, palace intrigues led to the accession of a younger son lacking his father's shrewdness and prodigious capacity for work. The strictly centralized system, in fact, required an exceptional ruler, and lacking traditional legitimacy or popular support, it rapidly collapsed. In the West, the most lasting legacy of the short-lived Qin dynasty is its name: Qin—which in Wade-Giles romanization is Ch'in and thus pronounced in English "chin"—is the origin of the English name China.

In China, lurid stories about the rise and fall of Qin Shi Huangdi and his empire continue to captivate the popular imagination, as shown in the 2001 movie (released in North America with English subtitles) *The Emperor and the Assassin*, directed by Chen Kaige. Much of this lore is based on the account

The reason why China suffers bitterly from endless wars is because of the existence of feudal lords and kings. • **Qin Shi Huangdi (c. 259–210 BCE)**

by the official Han dynasty historian, Sima Qian (c. 145–c. 86 BCE), which was not only written over a century later but also reflects pro-Han, pro-Confucian sentiments. The historical Qin Shi Huangdi may or may not have been as cruel, paranoid, and arrogant as he is depicted. But one indisputable piece of physical evidence attests to the grandiosity of his ambitions. In the 1970s construction workers near the modern city of Xi'an discovered enormous underground chambers with thousands of life-sized statues of soldiers and horses. This terracotta army, left to guard the First Emperor forever, has become a national monument and first-class tourist attraction. The emperor waits nearby, his tomb encased in an artificial mountain. When it is excavated, Qin Shi Huangdi will probably achieve even more historical celebrity—or notoriety.

Quinine

Quinine, the great antimalarial medicine, was the first disease-specific treatment in the Western medical arsenal. Unlike earlier medicines that only masked or relieved the symptoms, quinine was capable of bringing about either a temporary or permanent cure, depending on the type of malarial infection.

Quinine, the first Western medicine to be targeted at a specific disease, was widely employed in western Europe and North America for generations before the germ theory of disease. In the nineteenth century it was the principal line of defense against the major public health threat of malaria in the United States and parts of Europe.

In 1820 the French chemists Pierre-Joseph Pelletier and Jean-Bienaimé Caventou isolated two alkaloids from the bark of the cinchona tree. They named the white crystal *quinine* and the brown liquid *cinchonine*. These and other successful laboratory experiments by Pelletier and Caventou mark the beginning of modern alkaloidal chemistry.

In the course of the 1820s, chemical manufacturing firms sprang up in the U.S., the Netherlands, Great Britain, France, and Prussia to produce quinine and cinchonine. Cinchonine became known as the “poor man’s quinine”; it sold at a fraction of the price of quinine and became part of patent medicine formulations. Quinine gained an international reputation as the effective cure for malaria, and the high demand for it yielded robust profits. Many of today’s major international pharmaceutical corporations have roots in the quinine industry.

Most early consumers were in the U.S. and in western Europe, where malaria was one of the principal

public health problems of the nineteenth century. Through the course of European colonial expansion and experience with the disease environment on the African coasts, malaria eventually came to be understood as a global disease. Quinine was extremely portable, and from the middle of the nineteenth century onward it was regularly taken as a prophylaxis, allowing European explorers, missionaries, and troops to carry out their activities in areas where malaria was endemic. In India, the British learned to take their quinine dissolved in water, with gin added, thereby creating the gin and tonic. Some authors have assigned a primary significance to the role of quinine in the European conquest of the tropics, but recent scholarship suggests that a variety of other public health practices, such as mosquito screening and latrine digging, were at least as important in reducing the rates of sickness and death in the tropics.

Beginning in the early twentieth century, quinine was employed in mass public health campaigns, known as quininization, designed to reduce drastically the toll of malaria through universal chemical therapy. This policy was first adopted in Italy, with considerable success. But the expense of the policy, in combination with the fact that quinine could not prevent relapses of all forms of malaria, led to a return to individual therapy and a focus on environmental interventions to destroy the anopheles mosquito, which carries malaria, and its habitat.

Quinine proved its importance to the military during the early twentieth century. Quinine could be crucial to keeping troops fit to fight, and reducing the enemy’s access to the drug could produce military victory. During World War I, the Allied powers cut off the supply of quinine to the Germans and thereby

Quinine was one of the medicinal poisons; one of the strongest of these. Four grammes could make one deaf and giddy and short-winded; it acted like atropine on the visual organs...it was as intoxicating as alcohol; workers in quinine factories had inflamed eyes and swollen lips and suffered from affections of the skin. • **Thomas Mann (1875–1955), *The Magic Mountain***

This illustration of a bottle of quinine tincture, and the plant it derives from, originally graced the back of cigarette box. New York Public Library.

produced great suffering along the Eastern Front. The Germans undertook an emergency scientific research program to find a synthetic substitute, but did not succeed until the 1920s.

Following World War I, the League of Nations Malaria Commission attempted to survey the global status of malarial infections and to estimate the amount of quinine that would be necessary to intervene effectively. The estimated quantity was in excess of the world's supply, and the initiative to treat the world's populations chemotherapeutically was dropped. This early survey and the problems encountered with mass chemotherapy, however, anticipated both the creation of the World Health Organization and the later problems of the global HIV pandemic.

The world's market supply of quinine during the 1920s and 1930s came to be controlled by an Amsterdam-based cartel known as the Kina Bureau, which succeeded in assuring a reliable supply of quinine at prices that allowed growers to avoid excessive competition. This system was shattered by the Japanese conquest in 1942 of the Dutch East Indies, where extensive cinchona cultivation was practiced. The Japanese captured the cinchona plantations that had produced most of the raw material for quinine production. Allied casualties mounted rapidly in the

Pacific theatre of the war, and a major scientific research program was launched in the U.S. to find a synthetic substitute.

Since World War II, synthetic antimalarial drugs have largely replaced quinine. Today, quinine remains a highly effective antimalarial drug, and in cases of synthetic drug-resistant malaria, it is the drug of last resort.

Race and Racism

Racism can be described as an extreme form of ethnocentrism (i.e., seeing one's language, customs, ways of thinking, and material culture as preferable). But instead of using cultural factors to mark differences that can be overcome if some are willing and able to adopt beliefs and customs of others, racial boundaries depend on perceptions of *physical* distinctions between human body types, which are seen to be expressions of innate, *biological* divergence.

A number of historians have argued that racial divisions and racist attitudes were already present in societies such as Greece and Vedic India in ancient times. In any meaningful usage, however, these ways of conceptualizing and responding to differences between human groups originated in an age of global expansion and cross-cultural interaction in the fifteenth and sixteenth centuries CE. This era saw the first sustained contacts between the Eastern and Western hemispheres as well as greatly intensified regional and intracontinental interactions among societies across the world. Like all of the other peoples involved in cross-cultural contacts in these centuries, the Europeans who traveled overseas to trade, explore, and proselytize were highly ethnocentric, that is inclined to see their languages, customs, ways of thinking, and material culture as preferable—if not superior—to those of the diverse societies they encountered in Africa, Asia, and the Americas. This very human propensity to emphasize *cultural* differences was much in evidence in ancient times among peoples such as the Greeks, who distinguished themselves from the “barbarians” because the latter could not speak Greek, or the Chinese, who viewed such

nomadic, pastoral peoples as the Turks and Mongols as uncouth and inferior because they lived in regions with too little rainfall to support the sedentary agriculture and sophisticated urban lifestyles that the Chinese deemed essential for civilization.

Racism can be seen as an extreme form of this ethnocentrism, which for a number of reasons explored below developed for the first time in the early modern era of expansion, and—at least in this time period—only among peoples of European descent. Rather than cultural markers of difference, which are malleable and can be overcome if some groups are willing and able to adopt the beliefs and customs of others, racial boundaries are based on perceptions of somatic or *physical* distinctions between human body types, which are seen to be expressions of innate, *biological* divergence. Although the physical attributes stressed by those who construct or adhere to beliefs in the racial distinctiveness of human groups have varied considerably by time period and the society in which they are nurtured, racist thinking has almost always encompassed convictions that some peoples are inherently superior or inferior to others and presumed—at least implicitly—that this state of inequality arises from innate and immutable differences in intelligence.

The Genesis of Race and Racism

Whether based on a sense of religious or material superiority, European ethnocentrism in the fifteenth and sixteenth centuries CE was blinkered and self-congratulatory, but it was usually not racist in any meaningful sense of the term. Until the late seventeenth century, humanity was seldom divided into

This page from an 1878 geography text sets forth a classification of races that remained popular well into the twentieth century.

clearly demarcated categories by European travelers or writers, and when attempts were made to distinguish human types, the criteria were invariably vague and inconsistent. Physical differences between peoples encountered overseas were, of course, frequently described in considerable detail. But even in reports of contacts between the fairest-skinned northern Europeans and the darkest peoples of the rain forest regions of Africa or coastal South Asia, differences in skin pigmentation or hair texture are often noted in a matter-of-fact way. Contrary to the arguments of a number of Western scholars, which themselves may be expressive of ethnocentric preferences, European travelers did not necessarily admire light-skinned peoples more than “tawny” or “black” ones. In fact, numerous explorers explicitly commented on the beauty or well-proportioned bodies of both males and females of peoples described as dark-skinned. For example, François Bernier, one of the most famous French travelers of the late seventeenth century, was one of the first writers to attempt to classify the different types of humans he had encountered in his peregrinations.

He had, however, very little to say about the basic human types that he proposed in a rather desultory way, and was a good deal more interested in ranking the peoples he had encountered according to which had the most beautiful women, which included at the top of his list relatively dark-skinned Egyptians and Africans. In a number of accounts by other Western observers, peoples described as tawny or black are ranked above their lighter-skinned neighbors in terms of their intelligence and the level of cultural development they have achieved. And few Europeans who traveled overseas made any attempt to link facial features or hair quality to more general assessments of a people’s aptitudes or intelligence. Like differences in culture, physical variations were usually linked to environmental influences rather than seen as innate products of reproduction and biological inheritance.

The Atlantic Plantation System, Slavery, and Racism

It is still not clear exactly when attitudes and responses that were genuinely racist first emerged. But decades of careful research on the Atlantic slave trade and slave societies throughout the Americas have thoroughly documented the connection between chattel slavery as it developed in the centuries of European expansion into the Atlantic world and the emergence of increasingly elaborate arguments for the inherent and immutable differences between peoples sold into bondage for the slave plantations of the New World and the Europeans who shipped them across the Atlantic and profited from their enforced servitude. Even though we cannot determine precisely when and why the belief in extreme differences between Europeans and Africans was first articulated, by the seventeenth century it was widely held by the Portuguese, Dutch, English, and other nationals deeply involved in the slave trade. And there can be little question that the socioeconomic conditions under which the Atlantic slave trade was conducted directly affected the widespread acceptance of arguments for the Africans’ innate, or racial, inferiority, and in some circles

One ever feels his twoness—an American, a Negro; two souls, two thoughts, two unreconciled strivings; two warring ideas in one dark body, whose dogged strength alone keeps it from being torn asunder. • W. E. B. Du Bois (1868–1963)

the conviction that they were a separate species from the rest of humankind.

Early, inchoate racist sentiments were to some degree elicited by extreme differences in skin color and other obvious (but not genetically significant) variations in physical appearance between both those who sold slaves and those actually reduced to slave status. But cultural differences were in most cases far more critical in shaping European attitudes toward different peoples and societies. These ranged from the Africans' alleged paganism—which was said to revolve around the “worship” of what the Europeans misguidedly lumped together as “fetishes”—to European disparagement of what they judged to be low levels of material development, based on everything from the coastal peoples' lack of impressive stone structures (including forts), large cities, powerful rulers, and strong states, to their indifference to semi- or complete nudity. These assessments were, of course, problematic in a number of ways. To a significant degree, for example, they were shaped by the fact that the slave traders concentrated their activities in coastal areas, where, due to environmental conditions and human choice, political power was in fact less centralized than in much of Europe, and building materials and modes of dress were well suited to hot and humid ecosystems rather than the colder temperate conditions in the lands from which the Europeans set forth. The few European explorers who traveled inland throughout the vast savanna lands of the Sudanic belt (the desert and semi-arid zone between the North African Maghrib and the rainforest regions of West Africa) before the nineteenth century encountered impressive cities—such as Jenne and Timbuktu (Tombouctou)—as well as states and armies often larger than those in Europe, extensive trading networks, monumental architecture, and Islam, a monotheistic religion that had emerged from the Judeo-Christian tradition, and thus—despite intense Christian-Muslim rivalry—one Europeans could relate to their own. Because so much of what the Europeans found in the interior of Africa matched their ethnocentric expectations regarding human achievement and worth, the African peoples of the

Sudanic zone were generally given more favorable treatment in Western writings. Until well into the nineteenth century, Europeans usually dissociated the peoples of the Sudanic zone from the racist strictures often directed against the peoples of the societies on the west and southwest coasts of the continent, where the slave trade was concentrated from the sixteenth through the nineteenth centuries.

Few of the European travelers, slave traders, merchants, or missionaries who became involved in ongoing cross-cultural exchanges with African coastal peoples had any real understanding of their complex, sophisticated social systems and religions or appreciation for their splendid art, music, and oral literature. In addition, most of the Africans whom Europeans came into contact with were either merchants engaged to varying degrees in the slave trade or groups and individuals who had the misfortune to be captured and marched to coastal entrepôts in bondage, where they would be sold to the Europeans and transported to plantation societies across the Atlantic. Not only were the enslaved understandably profoundly disoriented and in states of shock and despair, they had been suddenly and violently snatched from the cultures where their skills were valued and they had won respect and social standing. In the Atlantic system, slaves were regarded as chattel, the property of other humans, and merely drudge labor. Even if they served as house servants on plantations in the Americas, they had no chance of becoming full members of the households and kinship networks to which they were usually connected in the largely domestic systems of slavery that predominated across most of Africa and Asia. Thus, there was little opportunity for most slaves to demonstrate their intelligence or talents. In fact, once enslaved, their burdens as laborers, and often their very survival, could depend on feigning incompetence or stupidity. “Smart” slaves were viewed with suspicion by members of the planter classes as potential troublemakers who might rouse others to resist the oppressive existence to which they had been condemned.

Whatever mix of these factors accounted for the emergence of racist attitudes among different

European groups operating within the Atlantic slave trading network, on the plantations of the Americas, or in drawing rooms of Europe where natural philosophers deliberated over the latest treatise on the divisions within the human species, racist ideas were regularly enlisted in the defense of the enslavement of Africans and the brutal systems of social control that were essential to hold them in bondage. Emphasis on the innate inferiority of the African “race,” or in extreme cases the contention that Africans were subhumans, served to rationalize the lives of humiliation, servitude, and misery that tens of millions forced to labor in the Atlantic plantation system endured through over four centuries. In these same centuries, far smaller numbers of Asian peoples, such as the Malays imported into the Dutch Cape Colony in South Africa or impoverished bonded servants from the lower castes of India, were also enslaved by Europeans overseas. But at least until the late eighteenth century, there were few attempts to argue for the racial distinctiveness of these groups. And those, such as the effort by the sixteenth-century Spanish jurist Juan Ginés Sepúlveda, who sought to demonstrate that the indigenous peoples of the Americas were soulless subhumans who could legitimately be enslaved, were fiercely contested—most famously by the Dominican friar Bartolomé de Las Casas, who energetically disputed Sepúlveda’s contention that wars to subjugate Amerindian peoples were just. Although in recent decades there has been considerable debate over the extent to which North American settler colonists distinguished themselves from the indigenous peoples in racial terms, the evidence suggests that until the nineteenth century at least, settler prejudice against the Native Americans was predominantly based on perceived cultural rather than physical differences.

Scientific Verification and Theories of Race

Until the last decades of the eighteenth century, racial distinctions and the concept of race itself remained vague and mutable. Early attempts to distinguish

basic types within the human species in the mid-seventeenth century were crude and impressionistic. It is believed that the first of these was by the humanist Isaac de la Peyrère who in a 1655 treatise on the descendants of Adam and Eve, chose skin color as his key marker and lumped most human groups according to whether they were reported as “red,” “yellow,” “black,” or “brown.” In the 1680s the indefatigable traveler François Bernier argued there were five main types of humans, including a catch-all “light-skinned” category and an equally variegated “African” grouping, and opined that the relatively minuscule Lapp herder peoples of the Scandinavian north composed a comparable category. Neither of these writers sought to set forth clear criteria on which these differences between human groups could be discerned and tested. A century later, a number of natural philosophers, most prominently the Scotsman Lord Monboddo, who had not even seen most of the peoples he wrote about, asserted that Africans, or Negroes, were closer (mainly on the basis of physical appearance) to apes than humans. In contrast to Lord Monboddo and other armchair naturalists, the physician Edward Long had lived for decades in the midst of the large African slave population in Jamaica. Large sections of Long’s *History of Jamaica* (first published in 1774) were devoted to descriptions of the unflattering physical features and signs of cultural debasement of the slave population that set them off from the European planter class. Like Monboddo, Long went to great lengths to chronicle the biological differences that made the Africans more akin to “lower” animal species than “whites.” But Long also argued at great length, and with considerable pretension to scientific authority, that miscegenation between Negroes and “whites” invariably resulted in infertile hybrids; thereby proving they were separate species.

In the last decades of the eighteenth century, a number of prominent scientists, including two Germans, S. T. Soemmering and Christopher Meiners, conducted extensive anatomical investigations of different human types, using mainly skeletal remains for which they had only limited non-European

samples. The purpose of these exercises in comparative anatomy was to provide an empirical grounding for determining specific bodily differences between racial groups and to establish more precise—hence ostensibly scientific—classifications of basic racial types within the human species. Popularized, and in many cases seriously distorted, by numerous nineteenth-century racist thinkers, including physicians who sought to refine or revise the findings of earlier investigators, racial classifications proliferated steadily. In some cases race studies were merged with “scientific” explorations of innate criminal types or utilized in tracts by eugenicists and other evolutionist thinkers arguing for the prohibition of race mixtures or promoting ones deemed advantageous for the improvement of dominant, hence superior races, whether “Caucasian” or “Mongoloid.” By the middle decades of the nineteenth century, the scientific study of race had fostered the production of a remarkable variety of instruments to measure the anatomical features of cadavers, skeletons, and skulls of specimens for different racial groups. Increasingly, the focus of these efforts to quantify racial distinctions came to be concentrated on the comparative measurements of skull samples from different human groups. By the last decades of the century, the “science” of phrenology was pervasive in European societies, a constant presence in venues as disparate as the ponderous deliberations of scientific societies and anthropological associations, such best-selling books as the Sherlock Holmes mysteries by Sir Arthur Conan Doyle, and the seaside amusement stands of Great Britain, where one could have one’s head measured in considerable detail for a small fee. The influence of evolutionary thinking, the assertion of Christian doctrine, and some of the more credible scientific studies led over the last half of the nineteenth century to the slow decline in the popularity of polygenetic explanations of racial difference, which traced them to separate creations, in favor of monogenetic theories, which stressed the essential unity of humankind, while attempting to argue ever wider, less permeable differences between racial types.

Racism and Ideologies of Oppression

In the half century before World War I and the two decades following the conflict, racial thinking reached the peak of its influence in shaping the ways in which societies in many parts of the world were organized, providing justifications for imperial expansion, supplying ideological fodder for mass social movements, and generating unprecedented intra-human strife and oppression. In the late nineteenth century, notions of racial superiority, often expressed in terms that were clearly nationalistic rather than biological, were constantly invoked by those who advocated colonial expansion and the domination of “lesser” peoples. Racist assumptions undergirded the civilizing mission ideology that was used to justify this aggressive behavior, explain away the marked decline in the living conditions of colonized peoples, and rationalize often draconian measures taken to repress popular resistance to imperial domination.

In colonies from Morocco to Vietnam, racist pronouncements informed all aspects of life from urban planning to schemes aimed at promoting the work ethic among the indigenous laboring classes. In the American South, South Africa, Australia, and New Zealand, many of the same ideas (though far less infused with scientific racism in the case of South Africa) provided the ideological basis for societies organized around extreme racial segregation and discrimination against people of color: African Americans in the southern United States; “kaffirs” or the Bantu-speaking majority in South Africa as well as immigrant Indians and mixed-race “coloreds”; Aboriginal people in Australia; and Maoris in New Zealand. In Germany, racist thinking intensified centuries-old religious and cultural prejudice against the Jews with ever more virulent expressions of anti-Semitism. After abetting the Nazi rise to power, racist invective made possible segregation, dispossession, removal and incarceration, and finally a massive, systematic campaign to exterminate not only the German Jews but all of those in the areas that were forcibly incorporated into the short-lived Nazi Empire from the late 1930s. In Japan in roughly the same decades,

ultra-patriotic ideologues who stressed the importance of racial purity as the key to the superiority of the Japanese people played critical roles in launching an increasingly militarized society on the path to external aggression, empire building, and ultimately a disastrous war against the United States and its European and Pacific allies.

Racism Repudiated and the Persistence of Prejudice

Those who sought to develop a science of race or promoted racist ideologies in the nineteenth and early twentieth centuries were no more successful than earlier thinkers had been in establishing meaningful, widely agreed upon points of demarcation between different human groups, much less in setting forth acceptable, non-ethnocentric standards by which the superiority or inferiority of different racial types might be judged. In the early decades of the twentieth century, when the influence of racist-charged ideologies and demagogues as well as racial discrimination at the everyday levels of social interaction remained pervasive in societies across the globe, an intellectual counteroffensive was mounted. One of the prime movers of this assault on racist thinking was Franz Boas, a prominent German anthropologist who spent the most productive decades of his distinguished career training graduate students in the United States, among whom were Margaret Mead and Ruth Benedict. Boas, the anthropologists his teaching inspired, and allied ethnographers challenged the widespread assumption that racism had been validated by objective, culturally neutral, scientific investigation. They also sought to supplant race or biological difference with an emphasis on cultural variations in the study of human societies. By the early 1940s, the genocidal nightmare that the Nazis unleashed across Europe in the name of race purity and the racially charged war then raging in the Pacific generated widespread revulsion against racist social and political agendas. In the decades that followed, the spread of movements for independence organized by colonized peoples across Asia and Africa, as well as civil rights agitation against

the segregationist regimes in the American South and South Africa, further discredited theories of racial difference and their use to legitimize discrimination.

Despite these countervailing trends and campaigns explicitly aimed at eliminating racial prejudice mounted by international organizations such as the United Nations, racism has persisted both in popular attitudes in many societies and, in some instances, state policy, such as the regime based on institutionalized discrimination that lasted in South Africa well into the 1990s. In some of the more militant, extremist strands of movements for liberation from racial oppression, such as some Black Power organizations in the United States and settler Zionism in Palestine, reactive racist sentiments were nurtured. Theories of race were also kept alive by scientists and social pundits who persisted in efforts to demonstrate empirically that there were genetic differences, centered on intelligence quotient, or IQ, averages, in the capacities of different human groups. But by the final decades of the twentieth century, the idea of race and the racist prejudices and behavior that had been associated with it for nearly half a millennium were rejected by the overwhelming majority of scientists and social thinkers worldwide.

Radio

Radio, or wireless, technology developed in the late nineteenth century and became the basis of a widespread broadcasting medium beginning in industrial countries during the 1920s. By the early twenty-first century, analogue AM and FM radio service was available in nearly every nation, and digital services were rapidly developing.

James Clerk Maxwell (1831–1879) was the first to make a theoretical prediction of a wireless means of transmitting information in the 1860s in Britain—and thus began a series of experiments that culminated in the widespread medium of radio, today available in nearly every nation. (Note that although *radio* can refer to any electromagnetic radiation, in this article the term is used for broadcasting and related services but not, for example, for television broadcasting signals, radar, or mobile phone service.)

The German physicist Heinrich Hertz (1857–1894) proved Maxwell correct with small-scale experiments in the late 1880s, but took the idea no further. The Italian inventor Guglielmo Marconi (1874–1937) began experimentation in the mid-1890s, and soon moved to Britain and interested the government and military in potential applications of wireless. In 1901 he transmitted the Morse code signal for the letter “S” across the North Atlantic. By then other experimenters had begun work with radio in Germany, the United States, Russia, and elsewhere.

Wireless telegraphy was first used to communicate with (and between) ships at sea and also for long distance (often transoceanic) links. Before and during World War I, wireless telegraphy was also applied to naval and military needs. Nations that

made effective use of radio (especially at sea) enjoyed a decided advantage over other countries. Japan beat the Russian fleet in 1904 at the Battle of Tsushima in part because of superior radio communications; British signaling failures at the Battle of Jutland in 1916 were due in considerable part to confused radio messages.

To transmit voice or music signals (wireless telephony as opposed to telegraphy) requires more complex continuous-wave transmitting equipment that developed only slowly in the first two decades of the twentieth century. Reginald Fessenden (1866–1932), a Canadian working in the United States, was one of the first to realize this important distinction and sought to develop the needed transmitter. Lee de Forest (1873–1961) had by 1906 developed his Audion, an improved vacuum tube which, it was eventually discovered, allowed amplification of electrical signals, and thus more effective transmitters and receivers. Edwin Howard Armstrong (1890–1954) developed several important wireless circuits that made effective radio receivers possible. Patent fights among these and other inventors often delayed radio’s progress. Few of them had radio broadcasting in mind.

Early U.S. Radio Broadcasting

What was probably the world’s first broadcast (that is, a noncode transmission sent out to all who cared to listen) took place in 1906 at Brant Rock, Massachusetts, south of Boston. Fessenden, using equipment of his own design, transmitted voice and music signals to witnesses and a small audience of amateur (“ham”) and government radio operators. Though he repeated the feat several times, he did not establish a

The cover of *Radio Broadcast* magazine from 1924 shows how easily the magic of radio can distract a person from the most mundane of chores.

continuing service. Others, including Lee de Forest offered occasional broadcasts, but again did not offer a regular service. That role fell to Charles D. Herrold (1875–1948), who in about 1909 began what is probably the world's first regularly scheduled radio broadcast service in San Jose, California. It expanded and continued until early 1917, when U.S. entry into World War I brought most private radio transmissions to a halt.

Radio broadcasting began in earnest in parts of Europe, Canada, and the United States between 1919 and 1921, as nations lifted their wartime bans on private use of wireless technology. The earliest stations were experimental affairs, often on the air for only a few hours a week and offering no set schedule. Equipment was often handmade. Few in the potential audience owned or knew how to make receivers. Only slowly did this change, as interest in and then demand for the new over-the-air service expanded. By the end of 1922 there were more than five hundred stations

on the air in the United States, all sharing a handful of frequencies.

The years 1927 and 1928 were crucial in defining U.S. broadcasting as a commercially supported and federally-regulated system. Receivers improved (easier operation, plug-in rather than battery power, and internal speakers), the first regular networks were established (NBC in late 1927; CBS a year later), programs became more standardized as to their variety, content, and length, advertisers were attracted to radio's growing audience, and preliminary audience research made clear the medium's growing availability and impact. Finally, federal regulatory standards and licensing were standardized and given enforcement teeth. The present AM band of frequencies was reserved for broadcasting, allowing many more stations. Radio's golden years were in the 1930s. Depression pressures made "free" radio (once you owned a receiver) a bargain when money was tight. Drama, comedy, variety, and eventually news programs were all honed to a high standard by late in the decade. Many companies using radio advertising enjoyed growing product sales. Radio programs were widely discussed and listeners identified with popular drama and comedy characters. Radio news became important by the late 1930s, edging out newspapers for breaking stories. World War II events were brought to home-front listeners thanks to improving technologies that allowed radio's reporters to broadcast live or recorded from battlefronts. On CBS, for example, Edward R. Murrow (1908–1965) and his colleagues broadcast vivid reports of wartime events home to U.S. listeners. Radio journalism was fully developed during the fighting in the early 1940s.

European Public Service Radio

In contrast to the U.S. commercial model, starting in the late 1920s, the British Broadcasting Corporation (BBC) established a very different approach of public service and noncommercial programming, becoming a model for radio systems in many other nations. BBC leadership saw radio as a means to improve the country and its people, and therefore

offered considerable culture, education, and arts programming, but not much light entertainment. Other European nations followed suit with their own domestic radio systems, and applied the same approach to radio in their colonial possessions. In the United States, on the other hand, public service radio before the 1960s was relegated to a small number of educational and noncommercial stations, most run by schools or universities. Radio was of greater social importance in Europe (because of its public service emphasis) than in the United States (where radio focused on musical formats) after the introduction of television.

By the start of World War II, radio systems in Europe, Africa and Asia (but not North and South America), were under some degree of government control, supported by fees paid by listeners (few carried advertising). For nations in which the government controlled radio systems, the purpose of radio was to advance national arts and culture and perhaps forward government policies. Little entertainment or popular music was offered, which led, along with advertisers' demand for access to listening audiences, to the formation in the 1950s and 1960s of numerous "pirate" (unlicensed) stations in Europe, some of them broadcasting from ships offshore, all following the American model by playing popular music and supported by advertising.

International Radio Services and Propaganda

Governments often co-opted radio broadcasting for the purposes of persuasion and sometimes terror. Radio Moscow in 1929 was perhaps the first international shortwave radio service; it was designed to extol the virtues of Communism beyond Russia. The BBC's Empire Service (the predecessor of today's World Service) to British colonies and French colonial broadcasting followed in 1932, as, after 1933, did Nazi Germany's radio service. The Nazi official Josef Goebbels (1897–1945) bent the medium to promote German superiority while striking fear into the hearts of potential enemies. The United States, which

had relied on private networks for international radio services in the 1930s (especially into Latin America), by 1942 formed the Voice of America, which became the official voice of the United States outside its shores.

Broadcast propaganda continued from all belligerents during World War II and expanded further during the Cold War as the Soviet Union, China, and several of their satellite states developed their short-wave radio systems and added airtime. The United States created Radio Free Europe and Radio Liberty in the 1950s to broadcast into Eastern Europe and Russia, respectively. Dictators sometimes made personal use of radio: the Egyptian leader Gamal Nasser (1918–1970) used radio extensively to reach his people in the late 1950s, as did Fidel Castro (b. 1926 or 1927), who made hours-long speeches regularly after taking over Cuba in 1959. Both leaders sought to strengthen their popular domestic support, often by attacking external enemies (and especially the United States). With the end of the Cold War in the early 1990s, international radio became somewhat muted, focused more on nationalistic messages and culture than on persuasion. Yet U.S. services into Cuba (Radio Martí) and the Middle East (Radio Sawa) demonstrated how international radio could still be applied to political and cultural persuasion. Cold War radio propaganda served primarily to keep true believers on both sides in line—it probably persuaded few listeners to totally change their thinking.

Radio in a World of Television

Postwar domestic radio broadcasting faced a changing media context worldwide. In the 1930s Edwin Armstrong had perfected FM technology, which largely eliminated static and offered far better sound and more predictable coverage. FM was a boon as Europe rebuilt its war-devastated radio systems, allowing more stations and diversified content. The service developed slowly into the 1950s in the United States as money was poured into new AM stations (which expanded from 900 in 1945 to 2,400 by 1952)

and television. FM radio was especially valuable in tropical countries, where electrical interference often drowned out AM's medium wave transmissions.

As commercial television expanded after 1950, however, radio soon shed much of its program variety (and, in the United States, its network service) to the newer television business. Radio became "background" to most listeners as it sought a new role—which turned out to be that of purveyor of modern popular music. "Formula" or "top-40" radio appeared in the mid-1950s in the United States as radio stations became jukeboxes for the latest musical fads, rapid-fire newscasts, and a growing amount of advertising. U.S. radio DJs (disc jockeys) became media heroes to millions—and models for the European pirate stations. A growing number of listeners used easily portable transistor radios after the mid-1950s, making radio the "take it with you" medium.

Educational radio became known as public radio in the United States after 1967, with National Public Radio being founded in 1969 to connect what would become hundreds of local outlets. National Public Radio and other program syndicators provided public affairs and cultural programs that stations used along with local expression and other alternatives to commercial pop music stations. By the late 1990s, more than a thousand small community FM outlets operated, largely with volunteer staffs. In the United States, FM radio's vastly better sound quality and programming made it more popular than AM radio by the 1980s; by the end of the century it was attracting more than 75 percent of the total U.S. audience. Music of all kinds was more likely to be heard on the growing number of FM stations (from 2,500 in 1970 to nearly 9,000 three decades later). By the 1990s, talk and news formats dominated AM stations, many of the most popular programs featuring conservative political commentators or religious broadcasters who paid for the time they used, just like advertisers. Such programs—much like international propaganda—tended to reinforce listener thinking, but probably persuaded a few to change their mind. Some political campaigns were clearly affected by such broadcasts, but evidence was

divided on their long-range impact. Radio became more widely available in automobiles as well (half of all cars had an AM radio in the early 1950s; by 1990 more than 95 percent had FM capability as well)—important because of the increasing number of "drive time" (commuting) listeners.

Deregulation of radio in the United States allowed ownership of national chains of hundreds of stations run by a single entity, while one owner could own up to eight stations in the largest markets. Considerable controversy arose as to whether this harmed or aided diversity of programming, but most observers agreed that deregulation contributed to the decline of news and public affairs programming on U.S. stations. By 2010, the commercial radio business was in financial trouble as advertising revenue declined and many listeners turned to alternative (and usually portable) audio sources. On the other hand, listeners of public radio news and public affairs programs appeared to be increasing.

After about 1990, the U.S. model of commercially supported popular music radio became more widespread worldwide. Some countries adopted competing public service and commercial radio systems as early as 1974 (in Britain) and even the 1940s (in Canada). Others moved away from noncommercial systems supported by government funding to a commercially supported structure, a move driven most by the need to conserve government money.

Radio's Digital Future

By the late 1990s, radio entered a lengthy transition from existing analogue AM and FM broadcast transmissions to digital transmissions. The latter are delivered from terrestrial stations in some countries, while in others (including the United States) satellites transmit digital radio programming on a commercial-free, subscription basis. Digital radio provides vastly superior sound quality but requires new receivers. After more than eight decades of service, sometime in the early twenty-first century analogue AM and FM radio services are likely to disappear in the face of these newer digital offerings. While changing

technology will make for clearer signals, there is no evidence thus far that it will either improve or diminish radio programming diversity or quality.

Railroad

Few inventions have had a more immediate or lasting impact on world history than the railroad. As the first mode of land transport capable of outpacing and outdistancing the horse and camel, it brought far-flung parts of continents and disparate peoples together for the first time. It became a potent symbol of modernity, technological prowess, and industrial know-how.

The railroad is a mode of transportation that consists of a locomotive, a train of passenger or freight cars, a two-railed steel track, a graded railbed, and terminals. Unlike other forms of transport, rail travel requires no steering: wheels with flanges (raised rims) keep the locomotive and cars on track. Railroads are energy-efficient because the wheels glide on the tracks with little friction.

A typical rail network consists of a trunk (main line) and branches (spurs). The trunk links the major urban and industrial centers along a roughly straight trajectory. Branches link the hinterland to one or more of the urban-industrial junctures on the trunk. Tokyo, Guangzhou, London, Cologne, Chicago, and New York are among the cities that have become major rail hubs, because they lie either in an industrial region, on the crossroads of multiple trunks, or near a seaport.

Steam engines were used to power locomotives for most of the nineteenth century, but modern engines run on diesel or electricity. Today's high-speed passenger trains, built by Japan, China, and France, can travel up to 300 kilometers per hour, faster than all other modes of transport except airplanes and spacecraft. The longest trip that can be undertaken without a change of trains extends 10,214 kilometers from

Moscow, Russia, to Pyongyang, North Korea. Only ships regularly transport people and cargo a greater distance. "The railroad," writer Heinrich Heine remarked in 1843, "annihilates space and only time remains."

The Origin of Railroads

Europe's mining enterprises began to utilize primitive rail systems to haul coal and iron ores as early as the sixteenth century. Because mine shafts were muddy and uneven, ore haulers placed parallel wooden rails along the mine floors to keep the cartwheels above the ruts. By the late eighteenth century, iron rails had come into common use and some enterprises had begun to extend their tracks from the mine entrances to the coal ports. These colliery railways were especially thick in the coal-mining regions of northeast England, near the Tyne and Wear rivers, where they were known as "Newcastle roads."

Most historians date the beginning of the "Railroad Age" with the opening of the 44-kilometer-long Stockton and Darlington Railway, a steam-powered freight line that cut the cost of coal transport by more than half, in 1825; and the 50-kilometer-long Manchester and Liverpool Railway, a passenger and freight line that linked two of England's most important urban-industrial centers, in 1830. Both were designed by George Stephenson, Great Britain's first great railroad engineer.

Railroad Mania in the Nineteenth Century

By the 1840s Great Britain was in the grips of a "railroad mania," a period of boom-and-bust

Claude Monet, *The Gare Saint-Lazare: Arrival Of A Train* (1877). Oil on canvas. Monet entered seven paintings of this railroad station in the fourth Impressionist exhibition in Paris, April 1877.

construction that led to a fourfold expansion in British tracks from 2,340 kilometers to over 9,700 kilometers within a decade. This period also witnessed the rise and fall of George Hudson, the “Railway Napoleon,” the first of many rail swindlers whose stock manipulations and shady dealings spawned numerous lawsuits, bankruptcies, and political scandals. “Britain is at present an island of lunatics, all railway mad,” Judge Cockburn declared in 1845 (Blum 1994, 14–15).

Railroad mania spread quickly to the coal-producing regions of northwestern Europe—Belgium, northern France, and Rhineland Prussia. This was where the world’s first international line was built, linking Liege, Belgium, and Cologne, Rhineland Prussia. Governments played a greater role on the continent than in Great Britain in promoting rail development and determining the routes. So did international bankers, most notably the Rothschild family, a name that became all but synonymous with continental rail construction in the nineteenth century. Government-business collaboration resulted in a construction frenzy, and by 1907 Europe (excluding Russia) was crisscrossed with 263,000 kilometers of track. Germany alone possessed 58,000 kilometers, followed by France (47,900 kilometers), the

Austro-Hungarian Empire (41,800 kilometers), Great Britain and Ireland (37,300 kilometers), Italy (16,600 kilometers), Spain (14,800 kilometers), and Sweden (13,400 kilometers).

Railroads also played a major role in achieving the nation-building ambitions of the United States, the Dominion of Canada, and czarist Russia. The first U.S. rail link, the Baltimore and Ohio Railroad, began operation in 1830, and for the next three decades construction occurred almost exclusively east of the Mississippi. The discovery of gold in California in 1849, however, put a premium on a fast and secure land route to the Pacific Ocean. Generous subsidies from the U.S. government made it possible for the Union Pacific and Central Pacific companies to jointly finish a line between Sacramento and Omaha in the years 1863 to 1869. Several other lines followed, including the Southern Pacific (1881), Northern Pacific (1883), and Great Northern (1893). Meanwhile, Canada completed the first true transcontinental railroad, the Canadian Pacific, which linked the eastern port of Montreal to the western port of Vancouver, in 1885. The Canadian Northern and Grand Trunk Pacific followed in the early twentieth century. Last, the Russian government constructed the Trans-Siberian Railway, linking Chelyabinsk

Rail travel at high speed is not possible because passengers, unable to breathe, would die of asphyxia. • **Dionysus Lardner (1793–1859)**

and Vladivostok, between 1891 and 1916. At 7,600 kilometers, it is still today the world's longest railroad. By 1907, the United States had laid a total of 382,100 kilometers of tracks (more than all of Europe combined), Canada 36,300 kilometers, and Russia 63,100 kilometers.

Colonial and Foreign-Financed Railroads

The Railroad Age coincided with the peak years of European colonization and imperialism, and consequently most of Africa's and Asia's early railroads were built with European capital and know-how. The British jump-started India's rail network in 1853, with the construction of a 34-kilometer-long line between Bombay and Thana, and by 1880 all of its major cities were connected by rail. Various European governments built lines in China, but construction proceeded at a snail's pace until the Qing dynasty finally bowed to the inevitable and commissioned a U.S.-trained Chinese engineer, Zhan Tianyou, to build the Beijing-to-Zhangjiakou line in 1905. By 1907, Asia possessed a total of 77,110 kilometers of tracks, not counting those portions of Asia under Russian control. British India alone accounted for 48,230 kilometers, followed by Japan (8,000 kilometers) and China (6,800 kilometers). During the same time period, Africa's rail network grew to 29,800 kilometers, most of it concentrated in South Africa (11,300 kilometers) and Egypt (5,600 kilometers). Cecil Rhodes's dream of a transcontinental Cape-to-Cairo railroad, however, remained unfulfilled.

In the Americas south of the U.S. border, national authorities and international investors together provided most of the impulse for the 80,500 kilometers of tracks that were laid there between 1846 and 1907. Argentina developed the largest network (22,100 kilometers), followed by Mexico (21,900 kilometers of tracks) and Brazil (17,300 kilometers). British entrepreneurs financed the most construction in Argentina and Brazil, while the Mexican government managed to finance many of its own tracks.

Technology, Organization, and Regulation

The success of the railroad depended on several key inventions, chief among them the locomotive. Richard Trevithick demonstrated in 1804 that a steam engine could be used to propel railcars, but it was not until the 1820s that George and Robert Stephenson constructed the first modern locomotives, the "Locomotion" and "Rocket," for use on Britain's rail lines. Other important breakthroughs include the sleeping car, developed by George Pullman (U.S.) in 1857; pneumatic brakes, invented by George Westinghouse (U.S.) in 1869; the automatic car coupler, patented by Eli Janney (U.S.) in 1873; the electric locomotive, invented by Werner von Siemens (Germany) in 1879; and steel rails and steel cars, which came into widespread use in the early twentieth century. Equally important for a fast, safe, and smooth ride were track lines that followed an even gradient despite changes in the terrain. Two inventions were particularly useful in this regard: the iron bridge, pioneered by Robert Stephenson in Newcastle in 1849, and the railroad tunnel, first used in the Italian Alps in 1871.

Organizational breakthroughs also played a major role in the success of the railroad. The first was the introduction of "Greenwich mean time" (railroad time) in 1840, which made it possible for rail companies to establish uniform timetables and for passengers to plan their trips and make their connections. The second was the use of the telegraph for purposes of signaling and traffic control, a necessity especially on one-track lines where the danger of a head-on collision was always present. Station managers, signalmen, switchmen, and brakemen were all as essential to a safe and trouble-free journey as the engineer.

Track width was the one major technological-organizational problem that was never fully resolved. Most European and North American railroads adopted the same track width used in Britain—1.44 meters (56.5 inches)—which came to be known as "standard gauge." Some countries, however, chose a "broad gauge." Russia and Finland picked 1.52 meters (60 inches), while Spain, Portugal, and India chose

1.68 meters (66 inches). “Narrow gauge” railroads (less than 1.435 meters) were also built, especially in mountainous regions. The chief advantage of a nonstandard gauge is that it offers some protection against a military invasion. The chief disadvantage is that it inhibits the free flow of goods and passengers across borders.

Impact on Society and Politics

The railroad displaced the horse-drawn carriage as the preferred mode of passenger travel as early as the 1840s because it provided a faster, safer, and more comfortable ride under all weather conditions. It also largely outcompeted the canal-and-barge industry for the transport of bulk commodities such as ores, grains, gravel, lumber, chemicals, and petroleum. Rail travel, in fact, proved so superior to all previous modes of transportation that by the 1870s it had achieved a near monopoly on the movement of persons and goods in all the major industrial countries. Monopoly led to price fixing, deceptive business practices, and rampant corruption—and eventually also to government regulations designed to restore a semblance of public trust and private competition. One of the earliest was the Interstate Commerce Act, passed by the U.S. Congress in 1887. Monopolistic practices also made the railroad one of the most hated symbols of foreign domination. “Nationalization” thus became one of the catchwords of anticolonial and anticapitalist movements in the colonial and developing world. Juan Peron, for instance, purchased Argentina’s railroad system from British investors shortly after coming to power in 1946.

Many nineteenth-century liberals and radicals welcomed the railroad as a tool for bringing the world together in peace and harmony, but rails proved equally useful as a tool of empire-building and warfare. In the Franco-Prussian War (1870–1871), the Prussian army skillfully used the German rail system to invade and conquer northern France. Russia’s decision to build the Trans-Siberian Railway through Manchuria was one of the principal causes of the Russo-Japanese War (1904–1905). Plans to construct

a Berlin-to-Baghdad Railway in the early twentieth century contributed to the outbreak of World War I in 1914.

The End of a Monopoly

The Railroad Age came to an end during the first half of the twentieth century with the emergence of automobiles, trucks, buses, airplanes, and pipelines as alternative modes of transport. Nonetheless, with some 1,204,000 kilometers of track on every continent except Antarctica (enough to encircle the earth more than thirty times), the railroad remains central to the movement of people and goods to this day. In densely populated regions, such as western Europe and Japan, rails are often as fast and convenient as autos and planes. Railroads also remain popular in India, China, and other parts of the developing world, where they are typically the only affordable means of travel. Because railroads require far less fuel than trucks, they are also still one of the most cost-effective methods for transporting bulk commodities.

Railroads experienced a small revival in the 1960s with the advent of the “container age” in the shipping industry and the development of high-speed trains. Flatbed rail cars loaded with containers now transport a portion of the finished products that were once carried almost entirely on trucks. Similarly, with the opening of the New Tokaido line between Tokyo and Osaka in 1964, railroads began to recapture a portion of the passenger traffic that had been lost to the airlines. The completion of the Channel Tunnel (“Chunnel”) in 1994, for instance, opened up a high-speed rail route between Paris and London that can be traversed in less than three hours.

Although as of 2009 the United States possessed the most usable miles of tracks of any country in the world today (233,000 kilometers), 143,000 were allocated for freight. Passenger traffic in the United States is minuscule (despite the advent of Amtrak service in 1971), compared with other countries whose highway infrastructures, dense urban populations, or economies do not support automobile commuting or ownership. Asia, meanwhile, accounts for nearly 70

percent of all railroad passenger miles worldwide, largely because millions of Indians and Chinese travel by rail every day.

China indeed seems to be the most ambitious railway builder today. Its overburdened system carried 25 percent of the world's rail traffic on 6 percent of the world's lines (86,000 kilometers) at the end of 2009. In an effort to boost its economy even further, China embarked on a construction program that will help shift the center of its economic focus inland; it aims to reach 120,000 kilometers of rail line by 2020.

Ramses II

(REIGNED 1304–1237 BCE)

EGYPTIAN PHARAOH

Ramses II, also known as “Ramses the Great,” was one of the most famous pharaohs of the nineteenth dynasty of Egypt (1570–1070 BCE). He established numerous building projects, conducted aggressive war campaigns, and created international ties that are still discussed today.

The Egyptian pharaoh Ramses II was born to Seti I and Queen Tuya in 1279 BCE. He is most often remembered for the ambitious building projects and aggressive war campaigns he conducted, and for solidifying Egypt’s legacy in the world. But it is possible that Ramses II may have had some connection with the exodus of the biblical text, as there is some discussion among scholars whether Ramses or his father was the reigning pharaoh at the time of the event. Although most agree that Seti I was pharaoh, no Egyptian texts mention any accounts of the Hebrew exodus. The stela of Merneptah, son of Ramses, however, does include the name “Israel” in a list of peoples conquered.

Ramses II began his reign at the age of twenty-five. In contrast to his grandfather Ramses I’s brief period on the throne (1293–1291 BCE), Ramses II led Egypt successfully for sixty-seven years. Not only did the king solidify Egypt’s legacy throughout the world, he secured his family legacy by fathering many children. As a result of his marriages and of relationships with women in his harem, Ramses sired more than one hundred sons and daughters.

Two of his wives, Nefertari and Istonfret, are known in Egyptian history, but there is not much information available regarding the background of either queen. Nefertari was Ramses’ first wife, and she gave birth to their initial child, the crown prince

Amenhirkhopshef. Their family also included two daughters, and three more sons. Nefertari died during the twenty-fourth year of his reign, and Istonfret became queen shortly thereafter. Istonfret also bore three sons, one of whom, Merneptah, would be the king’s successor. Primarily for political reasons, Ramses made international connections by marrying women from surrounding nations or having them become a part of his harem.

The powerful pharaoh was also a great military strategist, a trait associated with his grandfather, who was also a successful army officer. During his time on the throne, Ramses II battled several enemies, but among the most notable Egyptian foes were the Hittites to the north. Seti I had success in maintaining peace with them, particularly at Egypt’s volatile Syrian border near the city of Kadesh. However, a revolt near Kadesh in 1275 BCE forced Ramses to take action against the Hittites. What followed is known as the “battle at Kadesh.” As the Egyptian forces slowly moved north to the city, it appeared that they would have little difficulty with the Hittites. They even captured two spies who divulged the Hittites’ attack plans, but the men were designated plants who purposely gave false information to the Egyptians. Consequently, Ramses’ men marched into a waiting ambush. However, by employing his cunning military skill, Ramses was able to maneuver his troops and eventually forced the Hittites to retreat. Within days the Egyptians and Hittites battled again to what most scholars interpret as a draw. Nevertheless, the inscriptions on the walls of the Ramesseum mortuary temple and the temples at Karnak, Abydos, Abu Simbel, and Derr show iconographic depictions of a triumphant Egyptian army slaughtering its Hittite enemies, and

View of colossal figures, probably Ramses II, carved into rock that is part of the Great Temple at Abu Simbul, Egypt. Albumen photograph taken between 1856 and 1860 by Francis Frith.

the writings sing the praises of Ramses' bravery and skill on the battlefield.

In addition to the ruler's military brilliance, the reign of Ramses II is further defined by colossal architecture and detailed sculptures found throughout Egypt. One of his greatest architectural marvels is the Great Temple at Abu Simbel. The facade of the structure has four seated figures of Ramses II. Each stands about 20 meters high, and they have been sculpted directly from the mountain where the edifice is located. The temple also demonstrates a unique feat of engineering in that when the sun rises on 22 February and 22 October the light shines through the entrance and illuminates three of the four gods seated inside. Like the statues of Ramses, the gods have also been carved directly from the mountain.

Ramses II's reign ended in 1237 BCE. Not only did the king lead the Egyptians successfully during his tenure as king, he lived more than ninety years. Sadly, the contents of Ramses's tomb, like those of many others, fell into the hands of robbers. Items such as bronze

and wooden *ushabtis* (figures shaped like mummies) and a statue of the king survived and are housed in museums throughout Europe. Excavators also discovered the pharaoh's mummified body, which now lies in the Louvre. Ramses II's magnificent accomplishments are firmly etched in Egyptian history.

Raynal, Abbé Guillaume

(1713–1796)

FRENCH HISTORIAN

Abbé Guillaume Raynal, in his influential, multi-volume work known as the *History*, thematically compared the experiences of European nations in the pursuit of global commerce, both in Asia and the New World. This eighteenth-century work inspired advocates of reform and even revolution on both sides of the Atlantic. A didactic work representative of its age, it nevertheless provided an agenda for modern excursions in world history.

The Abbé Guillaume Raynal was the primary author of *Philosophical and Political History of the European Settlements and Commerce in the Two Indies*. This book, known as the *History*, was a multivolume exploration of European expansion in the East and West Indies, as Asia and the Americas were then designated. One of the most popular and influential works of the eighteenth century, this collaborative venture appeared in three major editions and many printings between 1770 and 1781. Like Denis Diderot's *Encyclopedia*, it was a laboratory of Enlightenment ideas and concerns with an agenda of opposing tyranny and ignorance. (The Enlightenment was a philosophic movement of the eighteenth century marked by a rejection of traditional social, religious, and political ideas and an emphasis on rationalism.) But the *History* was more thematic in comparing the experiences of European nations in the pursuit of global commerce both in Asia and the New World. Raynal focused on the methods by which colonies and trading stations were established, the impact of colonialism on the indigenous cultures, and the effects of imperialism on European countries. Beyond his comparative

and global perspectives, what also connected him to twentieth-century approaches to world history was his inclusive concern with elements of both material and nonmaterial culture. He was just as fascinated by the products of commerce and the geographical conditions of commercial intercourse as he was by the principles of colonialism.

Raynal was joined in his enterprise by various Enlightenment figures, the most important being the co-editor of the *Encyclopedia*, Denis Diderot. Diderot's more radical vision was increasingly prominent in the *History* editions of 1774 and 1781 and was especially prominent in the attacks on slavery and political oppression. Raynal also relied on numerous printed sources and the reports of colonial administrators, traders, and persons of learning with whom he had contact. Raynal himself traveled only through his writings.

Although the *History* was interspersed with anecdotes and digressions, its organization reflected the direction announced in the title. Beginning with the East Indies, Raynal described not only the Portuguese, Dutch, English, and French expansion in Asia, but also the lesser roles of Russia, Prussia, and Sweden. China and India were given extensive treatments, and then the focus shifted to the West Indies and descriptions of the Spanish and Portuguese conquests and colonization in the New World. In the following books Raynal and his collaborators examined French and British colonization in the Antilles and then in North America. Slavery and the slave trade were central to this discussion. The last book of the second and third editions constituted an overview of the moral and philosophical underpinnings that characterized much of the *History*. Such topics

Pages from the first edition of *Esprit de Guillaume-Thomas Raynal* (tome premier, 1782).

as religion, morality, tariffs, public credit, population, commerce, and agriculture were followed by a final theme, “Reflection on the benefit and harm which the discovery of the New World has done to Europe.”

The Jesuit-trained Abbé Raynal (an abbé is a member of the French secular clergy) embraced progressive Enlightenment ideals, even though the editions of the *History* and several of his minor works betrayed many shifts and inconsistencies in his positions. He shared the popular ideology of the French economists known as “Physiocrats” in advocating free trade, the elimination of commercial monopolies, and the advantages of free labor over slavery. Indeed, although Raynal came to represent a gradual approach to emancipation, contemporaries viewed the *History* as an oracle of the antislavery movement. A foe of the extremes of political absolutism and popular government, he seemed to have preferred some form of constitutional monarchy. Some of Raynal’s harshest criticisms were leveled at the claims of religious systems, such as the Catholic Church’s doctrine of papal infallibility, which he felt had led to intolerance and fanaticism.

Raynal’s *History* was perhaps the last example of the cosmographical tradition, begun by Andre Thevet and Sebastian Muenster in the sixteenth century,

which attempted a global comparison of cultures. They anticipated Raynal in explaining the rise of Europe in part as a result of utilizing such technologies as the compass and the printing press. Yet, he went much further in championing eighteenth-century ethnocentric perspectives that celebrated Europe’s ascendancy and the benefits of European culture for indigenous societies, even recommending, in the third edition of 1781, mixed marriages between French subjects and colonial natives as a way of further civilizing the latter. Although he gave considerable hearing to the debate about the virtues of primitive culture versus civilization and expressed humanitarian concerns about various societies the perspective of the *History* was clearly Eurocentric.

As much as any single literary production, Raynal’s *History* mentored the advocates of reform and even revolution on both sides of the Atlantic. A didactic work, clearly representative of its age, it nevertheless provided an agenda for modern excursions in world history.

Red Cross and Red Crescent Movement

The Red Cross and Red Crescent Movement, with agencies in over 178 countries around the world, aims through humanitarian intervention and international law to help victims of war and armed conflict (on a local or international scale) or to aid those afflicted by natural and human-caused disasters.

The International Committee of the Red Cross (ICRC) and the International Federation of Red Cross and Red Crescent Societies (the Federation), together with the national Red Cross and Red Crescent Societies in over 178 countries around the world, form the International Red Cross and Red Crescent Movement. As a whole, the Movement's mission is to help victims of international and local armed conflicts and to lessen the horrors of war indirectly through international law and directly through humanitarian intervention. The larger movement also undertakes the peacetime relief of suffering from natural and humanmade disasters. There are currently over 250 million members of the Red Cross Movement.

Perhaps more than any other international organization, the Red Cross has been able to shape international behavior. Working through the international legal system with the Geneva Conventions (first developed in 1864, and adopted in their current form in 1949) and other treaties, the Red Cross has created what is now almost universally recognized as correct humanitarian behavior in wartime: neutrality for medical personnel and their equipment and the humane treatment of prisoners of war. The ICRC considers itself the "guardian of international humanitarian law" and works to extend the reach and observance of those laws. The success of the international body has been aided by the local importance of the national societies.

The International Committee of the Red Cross

The ICRC is the original, earliest Red Cross group, founded in 1863 by Jean-Henri Dunant (1828–1910), who was honored for this accomplishment in 1901 with the first Nobel Peace Prize. The ICRC, an independent organization that remains small and almost unchanged since the late 1800s, is a non-governmental organization staffed almost entirely by citizens of Switzerland, a policy intended to

A portrait of Clara Barton, founder of the American Red Cross Society, painted in 1844 by Henry Inman.

Emblem of the International Federation of the Red Cross and Red Crescent Societies.

safeguard the neutral political stance of the organization. These 800-plus “delegates” conduct business for the Committee around the world. The group’s main responsibility is to work as a neutral intermediary in situations of armed conflict, protecting both military and civilian victims, as well as mobilizing and organizing the national societies to assist its work. Comprising fifteen to twenty-five members who make policy for the Committee, the ICRC is technically a private Swiss company, headquartered in Geneva, Switzerland, where its archives and offices are located.

The Federation and the National Societies

The Red Cross and Red Crescent Movement is augmented considerably by the work of the national societies, self-governing organizations that today exist in over 178 countries (the societies in Taiwan and Israel are not recognized by the ICRC). These groups are funded by membership fees and popular subscriptions, although in many countries, government subsidies provide much of their monies. Each national society has a unique character and history, linked to the national history of the country in which the society was founded. For example, the American Red Cross Society was a latecomer to the Red Cross organization. It was founded in 1881 by Clara Barton and chartered by Congress in 1900, and modeled on the Japanese Red Cross Society, which was the preeminent Red Cross society in the world at the

A young woman in a Red Cross uniform, circa 1880–1923, Sydney, Australia. Tyrrell Photographic Collection, Powerhouse Museum.

time. Many national societies sponsor public health programs, as well as provide disaster relief and assist the ICRC in war relief.

The International Federation of Red Cross and Red Crescent Societies, like the ICRC, is an international group with headquarters in Geneva, representing the national societies and coordinating their mutual help, cooperation, and program development. Proposed after World War I by American Red Cross War Committee president Henry Davison, it was founded in 1919 as the League of Red Cross Societies. The League changed its name in 1983 to the League of Red Cross and Crescent Societies, to include Muslim nations unwilling to adopt the sign of the cross, and finally in 1991 became

the International Federation of Red Cross and Red Crescent Societies.

The Red Cross Movement: Perspectives on the Future

In the past 140 years, the Red Cross has grown from a small group of visionary European men intent on lessening the destruction caused by war to a worldwide movement including and serving people on all continents. The movement has been unusually successful in educating states and individuals in its principles, principles it claims are universal: humanity, impartiality, neutrality, independence, voluntary service, unity, and universality. The Red Cross symbol is perhaps the most widely recognized symbol in the world, known to people of all nations as a beacon of medical aid and relief. The success of the Red Cross mission is encouraging for those hoping to create an

international society that has the moral weight to influence the behavior of states and individual actors.

Religion and Government

Religion has traditionally served as a source of authority, law, and moral norms for society, even in predominantly secular societies. Through most of the world's history, religious traditions have had formal ties with governments and have been seen as an important source of legitimacy of rulers.

Religion and government have often existed in complementary roles throughout world history—with religion lending authority to a government, and government legitimizing a leader's rule. Various societies throughout history have practiced toleration or acceptance of minority faiths, although only rarely based on principled beliefs in religious freedom. Modern ideas of rights to religious freedom and secular governmental systems are based in a variety of sources, but draw great strength from the Western church-state tradition and the Enlightenment.

Religion: Source of Law, Authority, and Moral Values

Throughout world history, religious traditions and beliefs have been a direct and indirect source of law and authority. The Babylonian Code of Hammurabi, for example, begins with a reference to the gods Anu and Bel, who called Hammurabi (reigned 1792–1750 BCE) to “bring about the rule of righteousness in the land.” The Jewish Law of Moses not only codified religious belief, but also set forth an extensive and elaborate legal system that governed all areas of social life. In more recent times, the Bible formed the basis for laws in the early American colonies and was used

to resolve issues as far-ranging as procedural rules, property law, criminal law, and, in general, the ideal of the rule of law. Even in modern secular societies, religion is still regularly used as the source for moral values and arguments for reform. For example, Reverend Martin Luther King Jr. (1929–1968) and Mohandas Gandhi (1869–1948) drew extensively on the Christian and Hindu traditions in their calls for social change, and similar religious beliefs have informed debates on the abolition of slavery, care for the poor, abortion, marriage, and other social and economic issues.

Traditional Religious–Governmental Ties

In the ancient world, religion was traditionally intertwined with ruling hierarchies, through either theocracies or divinely ordained rulers. In the Chinese Confucian tradition, for example, emperors were believed to have the Mandate of Heaven, sanction from a divine power that justified a ruler's actions as long as it was beneficial to those he ruled. Roman emperors claimed to be descended from the gods or to be gods themselves, as did Egyptian pharaohs. The Japanese emperor served as the head of the Shinto tradition. In the caste systems of the Vedic and Hindu traditions in India, the priests were traditionally the highest castes. Roman Catholic popes ordained the Holy Roman Emperors and Protestant kings claimed a divine right to rule. From the time of Byzantium, Orthodox countries were marked by caesaropapism, a system in which the head of state has authority over the church. Ties such as these conferred legitimacy on the rulers and gave religion an important

God is on everyone's side . . . and in the last analysis, he is on the side with plenty of money and large armies. • **Jean Anouilh (1910–1987)**

The remains of a large kiva at Pueblo Bonito, New Mexico, suggest that the structures within the kiva were used for community meetings as well as for religious ceremonies.

role in ensuring the community's stability, unity, and compliance with law. For example, a strong, unified religious tradition was seen as playing an important role in ensuring the binding power of oaths and contracts. The close association of a religious tradition with the ruling hierarchy was usually also associated with political privileges for the favored religion and limitations or bans on the practice of minority religions.

Experiences of Religious Tolerance

Despite the tendency for governments with strong religious ties to limit protections to a favored religion, some rulers throughout history have accommodated and tolerated minority religious traditions, although this tolerance was not always principled and was often limited by the perceived needs of

the sovereign. In many cases, tolerance served as a practical way to handle a multiethnic, multireligious empire. For example, the Persian Empire from Cyrus II (reigned 559–530 BCE) to Darius I (reigned 522–486 BCE) employed a policy of religious toleration and support for minority groups, allowing the Jews to rebuild the temple in Jerusalem and returning images of Babylonian gods to their sanctuaries in Babylon. The Mongol Empire created by Chingghis (Genghis) Khan (c. 1162–1227 BCE) practiced toleration of Buddhists, Christians, Confucians, Daoists, and Muslims, and the Qing dynasty in China (1644–1911/12) maintained a general policy of religious toleration toward Jews, Muslims, and Christian missionaries until antiforeign and anti-Christian sentiments led to the expulsion of foreign missionaries from China in 1720. The Muslim Ottoman Turks developed a “millet” system in which

other “religions of the book,” that is, Christianity and Judaism, could be practiced and had some self-rule, albeit with significant discrimination. The Peace of Westphalia (1648) at the end of the European Thirty Years’ War established limited religious tolerance in which believers had time to leave their country and move to one that supported their religious beliefs.

Principled Conceptions of Religious Freedom

In contrast to tolerance or acceptance of religious minorities by the grace of the sovereign, rulers and governments have only occasionally developed a principled basis for protecting the beliefs of others. In most cases, this basis itself has come from the religious beliefs of the ruler. For example, Asoka, the last major emperor in the Mauryan dynasty of India (reigned c. 265–238 or c. 273–232 BCE), adopted Buddhism and then promoted religious tolerance through his “Rock Edicts” based on the Buddhist idea of dharma. Anabaptist preacher Balthasar Hubmaier (1485–1528 CE) argued against the coercion of heretics or nonbelievers and wrote a defense of religious freedom based on the Bible. Roger Williams (c. 1603–1683 CE), the founder of the American colony of Rhode Island, wrote passionately in support of religious freedom and the separation of church and state, both based on his understanding of the Bible. Despite his own strong religious convictions, he opened the colony of Rhode Island to people of all faiths, where they were welcome to freely practice their beliefs. During the Second Vatican Council, the Roman Catholic Church adopted a policy statement, *Dignitatis humanae* (1965), which endorsed religious freedom and the independence of church and state based on religious reasons such as human dignity.

While some thinkers and religious leaders in some traditions still struggle with a principled basis for religious tolerance, modern scholars from all major religious traditions have identified resources within their own traditions that could support a principled belief in religious freedom. Drawing on worldwide legal, philosophical, and religious beliefs, the

Universal Declaration of Human Rights, adopted by the United Nations in 1948, supports the right to “freedom of thought, conscience and religion,” which includes “freedom to change his religion and belief and freedom, either alone or in community with others and in public or private, to manifest his religion or belief in teaching, practice, worship, and observance.” (Stahnke and Martin 1998, 59).

Much of the contemporary strength of the concept of religious freedom as a human right and the role of a secular state, however, comes from the Western tradition. The growth of Christianity in the originally pagan Roman Empire led to a system of “two kingdoms,” where both the emperor and church leaders exerted power over the faithful. The competition for power between the Roman Catholic Church and the Holy Roman Empire escalated in the middle ages under Pope Gregory VII (c. 1020–1085), who forbade the appointment of bishops by kings in 1078. This controversy, referred to as the Investiture Contest, strengthened the power of the church vis-à-vis the state. This contest for power, together with Western Christian notions of an independent duty to obey one’s conscience and natural rights, laid the groundwork for modern conceptions of a limited government and individual rights to religious freedom. Enlightenment scholars, such as John Locke in his famous *Letters on Toleration*, also advocated religious freedom and argued for the limited competence of governments in the field of religion, based on both philosophical and pragmatic reasons. The search for religious freedom was an important factor in the founding of the American colonies and was first embodied in a written constitution in the First Amendment to the U.S. Constitution. While religious freedom has since been enshrined in many national and international legal norms, many governments still significantly limit religious freedom.

Although most modern governments are primarily secular in nature, religion still plays an important role in government and society. For example, religious traditions still often serve as a source of reform and law. Religion traditions and emblems still provide important ceremonial and spiritual influences

Religion is regarded by the common people as true, by the wise as false, and by rulers as useful. • **Seneca the Younger (4 BCE–65 CE)**

in most countries. Unlike the United States, most governments still have formal, institutional ties, often including subsidies and other forms of state cooperation. Religious buildings, social services, or workers may be supported by the state and may serve as a resource in times of national crisis or on public holidays. Even in more separationist governmental systems, such as the United States and France, religious leaders often serve as chaplains in the military, prisons, and hospitals. While individual countries may have particular historical or cultural ties with a single religious tradition, most governments with cooperationist or accommodationist systems allow multiple religions to obtain government benefits and cooperate with the state. Despite the wide variety of current structures of the relationship between religion and governments and the many remaining challenges to religious freedom, a range of accommodationist and cooperationist systems throughout the world still preserve religious freedom.

Religion and War

War and religion are universal historical phenomena, occurring in nearly all places and all time periods. It should not be surprising, then, to find that the two have a long, complex, and varied historical relationship—one which is sometimes antagonistic, at other times mutually supportive, and often deeply ambivalent.

Warrior gods played a central role in the pantheons of many early religions as civilizations struggled to subdue the cosmos and, often, their neighbors. The war god Indra ranks among the most prominent Vedic divinities; the warrior god Marduk is the hero of the Babylonian creation epic, *Enuma Elish*; the war gods Ares and Mars, respectively, populate a host of Greek and Roman myths; and the war god Thor wages battle in ancient Norse mythology. War and religion, for better or worse, have gone hand in hand throughout history.

In many ancient civilizations—including Indo-Aryan, Greek, Egyptian, Babylonian, Hittite, Roman, Aztec, Crow, Norse, and Celtic—war was considered a fact of life and heroes were divinized. Religious epics emerged surrounding the exploits of human (if at times legendary) war heroes such as Arjuna (Hindu), Achilles (Greek), Arthur (Celtic), and Siegfried (Norse). Being a warrior was socially prestigious in cultures such as Indian (where the warrior class, the Kshatriya, ranked high in the Hindu caste system), Crow (where the warrior's raiding activities provided him with access to valued economic goods, most particularly horses), and ancient Babylonian (where male warriors were often rewarded with the society's most desirable female partners). Even great spiritual leaders could, at times, take up the sword

and lead armies (for example, Joshua in Judaism and Muhammad in Islam).

But even in cultures that valued war and warriors, the religious attitude toward them was often one of ambivalence. In the Hindu caste system, the priest (*Brahman*) ranked above the warrior. Holy men enjoyed a similarly elevated social standing in Crow and Babylonian cultures. In Greek mythology, war was as often seen as the source of tragedy as it was of glory. According to the anthropologist C. Scott Littleton, "The role of the warrior... was steeped in paradoxes. He was at once at the apex of the social order and a potential threat to that order. Indeed, the contradiction here, which is reflected throughout Indo-European religious beliefs, is inherent in the profession of arms: it involves a social institution dedicated to the destruction of society" (Littleton 1987, 345).

The histories of many of the major world religious traditions evidence a continuing struggle to come to grips with this paradox. In the process, the phenomenon of war has come to play a major role in defining, distinguishing and, at times, dividing particular religions, while the phenomenon of religion has come to give meaning and inspiration to war.

Judaism: Debating the Warrior Ethic

Judaism was founded in the ancient Middle East where warfare was the norm. The earliest Jewish texts, which probably stem from the mid-to-late second millennium BCE, reflect this violent reality. In Genesis, Yahweh (the ancient Hebrew term for god) is said to have told Abraham: "Know this for certain, that your descendants will be aliens living in a land

Hans Memling, *The Archangel Michael* (c. 1479). Oil on wood. As the “field commander” of God’s Army, Michael figures prominently in the book of Revelation fighting against Satan. Wallace Collection, London.

that is not theirs; they will be slaves, and will be held in oppression there for four hundred years. But I will punish that nation” (Genesis 15:13–24). Yahweh promises the Jews the lands of “the Kenites, Kenizzites, Kadmonites, Hittites, Perizzites, Rephaim, Amorites, Cannanites, Gigrashites, Hivites, and Jebusites” (Genesis 15:19–21). Much of early Jewish history consists of the ensuing, often exceedingly bloody, battles between the Jews and these various peoples. The book of Joshua in the Hebrew Bible records the story of the conquest of Canaan in which, at God’s bidding, the Israelites burn entire enemy cities to the ground, slaughtering all inhabitants—men, women, and children alike. As the biblical scholar Millard Lind writes, “Yahweh is a God of war. . . . Violent political power is thus a central issue in Israel’s experience of Yahweh” (Lind 1980, 24).

Yet existing side-by-side with these violent episodes is a deep-seated Jewish reluctance to embrace the warrior life. Speaking of Abraham, Moses, and other seminal figures in the history of Judaism, the nineteenth century German scholar Julius Wellhausen writes, “It is remarkable that the heroes of Israel . . . show so little taste for war” (Lind 1980, 34). The Jewish hero of the Exodus account, Moses, does not, with a warrior might, destroy the Egyptian army as it pursues the Jews; Yahweh drowns the army with Moses as a bystander. Powerful Jewish kings like David and Solomon are as often chided for hubris as lauded for their might. While Jewish history speaks of nationhood, land, and national destiny, its prophets more often speak of peace: “They shall beat their swords into mattocks and their spears into pruning-knives; nation shall not lift sword against nation nor ever again be trained for war” (Isaiah 2:4).

These two rival attitudes toward war emerge repeatedly in Jewish history. The Maccabean revolt in the middle of the second century BCE pitted Jewish rebels against their Greek oppressors. When the Greeks, led by Antiochus Epiphanes, attempted to stamp out Judaism by forbidding all Jewish practices and desecrating the temple in Jerusalem, the Jews, led by the Maccabaeus family, rebelled, eventually recapturing Jerusalem and reconsecrating the temple

(an event celebrated in the Jewish holiday Hanukkah). While the rebellion was doubtlessly violent in nature—some scholars see it as an early instance of successful guerilla warfare—a number of Jewish historians emphasize the fact that it was a group of nonviolent Jerusalem Jews who brought the ultimate victory. By peaceably withdrawing into the wilderness in response to the Greek actions and taking their tax “dollars” with them, these Jews, it is argued, forced the Greeks to relent and to accept Jewish worship practices in Jerusalem. Jewish scholars also point to the fact that the passage from Zechariah that is traditionally read on the Sabbath of Hannukah declares: “Not by might and not by power but by my spirit, saith the Lord of the Hosts” (Ferguson 1978, 86).

The ambivalence in Judaism concerning participation in warfare and the use of violence continues to this day in the emotional and often divisive Jewish debate over the proper response by the state of Israel to challenges posed by Palestinians and their fight for statehood.

Christianity: Pacifism, Crusades, and Just Wars

The religious ambivalence toward warfare is perhaps nowhere more graphically evidenced than in the history of Christianity, as adherents of the religion have, at different times (and sometimes simultaneously), embraced pacifism, “holy” crusades, and “just” wars (that is, a war limited by strict moral principles).

For the first three centuries following the crucifixion of Christ (c. 30 CE), the Christian church was almost exclusively nonviolent. Founding its actions upon the teachings of Jesus to love the enemy and Jesus’ refusal to take up arms in order to fight the Romans or even to prevent his own arrest and execution, the early church opposed killing and warfare. Whereas the Roman gods were seen as advocates of the Roman people in their battles against foreign foes, the influential Christian Bishop Clement of Alexandria (d. c. 215) writes in the second century, “Divinity now pervades all humankind equally...deifying humanity” (Pagels 1988, 39).

Christianity’s minority status within the powerful Roman Empire—until 312 CE, Christians constituted no more than 10 percent of the population of the Empire and were periodically subjected to savage persecution at the hands of the state—provided an additional (and, some scholars say, more practical and hence decisive) reason for the Christian rejection of war. As the religious scholar Elaine Pagels (1988, 39) writes: “Christians had discovered a terrible secret: the powers behind the Roman magistrates are not gods...but demons, active evil forces bent upon corrupting and destroying human beings.” The state meant death to Christians. As such, Christian complicity in the state, and in the institution of war, was largely rejected and pacifism was embraced. A minority of Christians—including members of most monastic orders, as well as denominations such as the Mennonites—continue to this day to reject all wars.

In 312, Constantine (c. 280–337 CE) became the first Christian leader of the Roman Empire and quickly legalized the practice of Christianity. In 381, Emperor Theodosius (c. 346–395 CE) made Christianity the state religion of the Empire, forbidding the worship of the Roman gods entirely. As Christians for the first time began to ascend to positions of political power, the religion began to consider anew the question of bearing arms. Aurelius Augustine (354–430 CE), the Catholic bishop of the city of Hippo in North Africa who is later canonized as St. Augustine, produced one of the most influential works in the history of Christianity, *City of God*, in which he argued that the state was an instrument provided by a loving God to help keep human sinfulness in check until Christ’s return.

While a kingdom of true and eternal peace will ultimately be established by God, in the interim “the natural order which seeks the peace of mankind ordains that the monarch should have the power of undertaking war if he thinks it advisable, and that the soldiers should perform their military duties in behalf of the peace and safety of the community” (Christopher 1994, 40). Augustine defines “just wars” as those which “avenge injuries...punish wrongs...or restore what has been unjustly taken” (Christopher

1994, 40). Augustine himself would come to advocate Christians participating as both soldiers and military commanders in wars to fend off the attackers of the Roman Empire, even though he acknowledged that grave injustices would inevitably be committed.

The notion of war as an instrument of the Christian God would reach its logical, if bloody, conclusion in the crusades. The crusades were a series of Christian military expeditions prompted by papal declarations and aimed, at least initially, at the recovery of the Holy Land from Muslim control. Initiated by Pope Urban II (c. 1035–1099) at the Council of Clermont in 1095 and extending for several centuries, the crusades promised participants the remission of their sins if they took up the cross and defended the faith. (The Latin word for cross, *crux*, is the root of the word “crusade.”) Tens of thousands of European Christians answered the call. Eventually this “defense” of the faith included attacks not only upon Muslims but upon all alleged enemies of the church, including European Jews and Christian heretics, with perhaps hundreds of thousands of people being brutally slaughtered in the name of Christ. One crusader reports, “Wonderful sights: piles of heads, hands, and feet. It was a just and splendid judgment of God that this place should be filled with the blood of unbelievers” (Baran 1998, 1).

With the end of the crusades, placed variously by scholars between the fourteenth and sixteenth centuries, came the rise of the Christian just-war tradition. Over the course of several centuries, so-called Scholastic authors such as Francisco Suarez (1548–1617) and Hugo Grotius (1583–1645) built upon the foundation established by Augustine and Thomas Aquinas (1225–1274) to develop a set of moral principles which, while allowing Christian warfare, attempted to place strict limits on its conduct—limits which presumably would prevent the barbaric excesses of the crusades. These principles, which would eventually serve as an important impetus for the founding of international law, consist of the *jus ad bellum*—rules which establish the circumstances under which Christians may enter war—and the *jus in bello*—rules covering the ethical conduct of war once it has been

initiated. Central to the *jus in bello*, for instance, is the principle of discrimination, which holds that Christians may kill even noncombatants as long as the deaths are unintentional: “The death of the innocent must not besought for its own sake, but it is an incidental consequence; hence it is not considered as voluntarily inflicted but simply allowed...” (Suarez 1944, 847–848).

In the twenty-first century, although Christians continue to debate various historical attitudes toward warfare, the just-war perspective has come to gain the support of the vast majority of individual Christians and Christian institutions, with *jus ad bellum* criteria such as “just cause” and “last resort” emerging as central aspects of public debate on initiating war.

Islam: War and Tolerance

Islam is often depicted as a religion that not only allows for but embraces warfare. In reality, the history of the religion is complex and surprisingly pluralistic with regard to issues of violence.

The Qur’an at times is clear in its support of the institution of war: “Warfare is ordained for you, though it is hateful to you; but it may happen that you hate a thing which is good for you, and it may happen that you love a thing which is bad for you” (Qur’an 2:216). Such passages combine in Islam with an important historical fact about the prophet Muhammad (571–632 CE): “Muhammad, it will be recalled, was not only a prophet and a teacher, like the founders of other religions; he was also the head of a polity and a community, a ruler and a soldier. Hence his struggle involved the state and its armed forces” (Lewis 1990, 49). In one of the most famous episodes in the founding of Islam, Muhammad flees his native city of Mecca in 622 CE, ridiculed and threatened by the town leaders for his religious teachings. Eight years later, he returns as a conqueror, leading an army of ten thousand into Mecca and converting the city in the process. As John Kelsay (1993, 45), a professor of religion at Florida State University, writes, “At least with respect to the example of Muhammad, then, it was possible to speak of the use of lethal force which

There will be peace on Earth when there is peace among the world religions.

• Hans Küng (b. 1928)

was right, in the sense of divinely sanctioned—even divinely commanded.”

The Abbasid caliphate during the classical period of Islamic civilization (c. 750–1258 CE) established an imperial state based in Baghdad and, employing the principles of divinely sanctioned war, ruled an empire extending from Egypt to Spain. During the Christian crusades, Muslim forces enjoyed a series of decisive victories over the crusaders, keeping much of the Middle East in Muslim control. Thus, although pacifism is found in some forms of Sufism (Islamic mysticism), mainstream Islam historically accepts warfare as a God-given instrument.

This does not mean, though, that war is accepted in Islam as a normal and acceptable condition. Far more of the Qur'an speaks of peace than of war: “The good deed and the evil deed are not alike. Repel the evil deed with one that is better. Then lo! He between whom and thee there was enmity will become a bosom friend” (41:34). Even the concept most often associated with the Islamic support of violence, jihad, literally translates from the Arabic as “striving” and not, as it is often translated, as “holy war.” In traditional Islamic thought, the “greater jihad” represents the striving of Muslims to overcome their own tendencies toward selfishness, hatred, and hubris; it does not mandate the slaughtering of infidels. Muhammad's triumphant return to Mecca is recast accordingly in some Islamic historical sources. In 630 CE, when Muhammad enters the city with his huge army, he asks the Meccan nobles who had threatened his life eight years earlier, “What am I to do with you?” Their leader, Abu Sufyan, replies: “The best.” With that, Muhammad frees all his rivals, in the process converting them to Islam by his generosity. In this strain of Islam, Muhammad rules by justice not fear, war is never initiated by Muslims, but fought defensively and reluctantly, and tolerance is among the highest values.

This moderate vision of Islam has guided much of the religion historically. When the Moors (a Spanish term for Muslim) crossed the Mediterranean to Gibraltar in 711 CE and conquered Spain, they ushered in a seven-hundred-year-long period not of oppression but of cultural flourishing, as Muslim art, architecture,

and ideas were peaceably integrated with those of the indigenous culture. The longest continually existing Christian community in the world exists not in Greece, Italy, or England; it is a Coptic Christian community in Egypt, a land dominated by Islam since 700 CE.

Islam's history with regard to war is thus more varied than many popular contemporary depictions in the West would suggest.

Hinduism: From Kshatriya to Ahimsa

War would seem to hold an unquestioned position of acceptance in Hinduism. The structure of the caste system suggests as much, with the Kshatriya (warrior) constituting one of the four main social classes. While classical Hinduism traditionally holds that all of creation is infused with a spark of the divine and killing is thus not to be taken lightly, the warrior's dharma (duty) to fight is consistently judged to outweigh this consideration. The *Mahabharata*, one of the greatest epic poems in all of world religious literature, examines the dilemma faced by the Kshatriya and concludes: “Since those evil actions belong to the duties of your profession, the penalty of evil karma will not attach to you” (Ferguson 1978, 29). In fact, the entire *Mahabharata* tells the tale of a great multigenerational war between members of the Bharata clan. In its most beloved segment, the *Bhagavad Gita*, the warrior Arjuna debates whether to fulfill his dharma to fight or his dharma to protect life, since the two seem to be incompatible; he is told by Krishna, an avatar of the great god Vishnu, quite directly: “Fight, O Bharata!”

Not surprisingly, then, war is common in the history of Hinduism. Candragupta and his son Samudragupta, two soldier-monarchs and unapologetic conquerors, established the Gupta Empire (320–484 CE), often viewed as the golden age of Hinduism. In the early eleventh century, when the Muslim Mahmud of Ghazna (971–1030 CE) invaded India, Hindus fought fiercely to defend the temple with, according to some accounts, fifty thousand men dying in a single battle. The Rajputs—calling themselves the “sword arm of Hindustan” and the

protectors of the Brahmins —emerged in the ninth century and have fought foreign challengers to Hinduism ever since.

There is a counterstrain in Hinduism, though, found in the Upanishads and other sacred texts. In the Chandogya Upanishad, *ahimsa* (nonharmfulness or non-violence) is seen as a foundational Hindu value, equal in importance to austerity, almsgiving, uprightness, and trustfulness. Mohandas Gandhi (1869–1948), the great spiritual and political leader of twentieth-century India, was the most influential advocate of *ahimsa*. In his teachings, Gandhi attempted to explain classical Hindu works that had for centuries been seen to support the warrior life as in fact embodiments of the principle of nonviolence. The *Mahabharata*, Gandhi argues, ends by depicting not the glory but the futility of war; Krishna in the *Bhagavad Gita* tells Arjuna to fight, but only as a means of illustrating to Arjuna the essential incompatibility of violent acts and the spiritual obligation to remain unattached to the “fruits of action.” Gandhi emerges with an approach to combating evil, which is both grounded in Hinduism and entirely nonviolent. As he writes, “I seek to blunt the edge of the tyrant’s sword, not by putting up against it a sharper-edged weapon, but by disappointing his expectation that I would be offering physical resistance” (Ferguson 1978, 38).

Hence, while Hinduism traditionally preserves a privileged place for the warrior, in recent decades a revisionist interpretation of Hinduism, founded on the rejection of war and violence suggested by Gandhi and others, has become highly influential.

Buddhism: From No Harm to the Warrior Ethic

Buddhism may well be the major religious tradition that has most consistently rejected warfare, but the history of even this religion is far from uniform.

The first of the Five Precepts of Buddhism, incumbent on monks and laity alike, is to not take life nor be a party to its taking. This prohibition applies equally to war, murder, and the killing of animals for food or ritual sacrifice. According to the *Dhammapada*,

“Everyone is afraid of violence; everyone likes life. If one compares oneself with others one would never take life or be involved in the taking of life” (Ferguson 1978, 47). The Buddha, Siddhartha Gautama (c. 566–c. 486 BCE), preached and lived by a code that mandated the causing of no harm, and he attracted many adherents to pacifism, both in his lifetime and beyond. The Maurya emperor Asoka (c. 270–232 BCE) was a military imperialist who, upon converting to Buddhism, established a welfare state, prohibiting all killing. The pervasive effect of the Buddha’s teachings with respect to pacifism can be seen in the harsh words of Yuan Tchen (779–831 CE), who chastises Buddhists for using their religion as an excuse for shirking military duty.

Yet the historical Buddha, born into the Hindu Kshatriya caste, is also regularly depicted as employing martial analogies, even after his awakening to Buddha status. *The Sutra of 42 Sections* records: “A man practicing the Way is like a lone man in combat against ten thousand....[S]ome retreat; some reach battle and die; some are victorious and return to their kingdoms triumphantly” (Sharf 1996, 45). The *Suttanipata* draws a distinction between accidental and intentional killing and, like the principle of discrimination in Christianity, condemns only the latter. In fact, all major strains of Buddhism, including both Theravada and Mahayana, contain important historical instances of support for war. In China during the Tang dynasty (618–907 CE), Buddhist monks were accorded military honors for their actions and, in 619, five thousand of them led a violent uprising that resulted in one monk proclaiming himself emperor with the title of “Mahayana.” In Korea, kings historically recruited thousands of Buddhist monks into the military—to fight the Mongols in the fourteenth century, the Japanese in the sixteenth, and the Manchus in the seventeenth.

After Zen Buddhism was introduced to Japan in 1192, it became the religion of the soldiered aristocracy and contributed to the emergence of the Bushido ideal, the way of the Samurai warrior. In the 1930s and 1940s, a series of Zen masters in Japan used the Zen notion that truth lies beyond reason (and that

there are thus no absolute moral principles) to excuse and even to support military aggression on behalf of Japanese imperialism, with Daiun Sogaku Harada Roshi (1870–1961) declaring, “The unity of Zen and war . . . extends to the farthest reaches of the holy war now underway” (Baran 1998, 1).

Thus, Buddhism, like Christianity, begins historically with a rejection of war and comes, over the course of centuries, to accept and even embrace warfare as an aspect of religious duty.

The Relationship Considered

Does war shape religion or does religion shape war? As the above examples indicate, the answer is almost surely both. Religious beliefs are often adopted and adapted to support political enterprises of various sorts, and warfare is a prominent instance of the political use of religion. But historically, religions have also used warfare as an instrument for their own advance, initiating wars or prompting others to do so on their behalf. While war remains an accepted part of the mainstream components of all the leading world religious traditions, it continues to raise the question pondered by ancient religions: is war the instrument of society’s preservation or the source of its destruction?

Religion—Overview

Religions are characteristically central in accountings of world history. While many people consider religion private, many are affected by its public presence. Religion supports empires and consoles victims. It inspires war and motivates warriors, but it can also be an agency of peace and the working of justice. The religious may be privileged as supporters of the state or hounded when they dissent.

Moderns have given the name “religion” to the many efforts through which people respond to what they experience or believe in as supernatural or suprahuman forces or beings. Exceptions in the form of purely humanistic religions are few. Most people in most cultures throughout most of history have given evidence that tending to religious matters is basic in their existence, and the energy they give to these has produced artifacts—temples and the like—and events, phenomena with which historians have consistently reckoned.

While religion may be what many modern people have come to call it—a private affair—it always has had a public presence. Individuals may be religious, but most of them form communities and these may collide with each other, attempt to exert power, and often turn out to be useful to civil authorities just as the religious communities find civil authorities useful.

Prehistory and Preliterate Cultures

Prehistoric and preliterate people could not and did not leave behind sacred texts of the sort that inform most study of religion throughout history.

Yet archaeology reveals numberless grave sites whose contents show that the living engaged in ceremonies and left articles suggesting their care for the dead and their concern for their afterlife existence. Some of this evidence in Europe and parts of Asia dates back over 70,000 years. Lacking texts, scholars have to deduce the meanings of the relics, but these demonstrate that religion is a constant and profound dimension of human life, so much so that many neuroscientists hypothesize that humans are “hard-wired” to seek meaning through rites and ceremonies, myths and symbols, ideas and behaviors, that they associate with the word religion.

One of the most common and, to those who uncover the altars and bones, most unsettling set of practices, has to do with human sacrifice. Castes of people, usually priests, were assigned the task of pleasing deities, for example the gods of fertility or weather or war, by offering their fellows or their captives on altars. Especially when such killing occurred in northern climates, as in Scandinavia, some corpses were so well preserved that scholars can deduce much about the way of life of the sacrificed and the sacrificers. While human sacrifice has virtually disappeared in modern times, it was long a factor in societies. In Aztec cultures in South America just before Europeans arrived and conquered them, thousands of their people had been ceremoniously sacrificed. In many ancient religions animals were substituted for people by those who wanted to win the favor of their deities. Bloodless sacrificial offerings, for example, gifts of money, remain favored ways of being religious into our own times.

Not only beginnings and ends, birth and death, fertility and burial rites occupied the religious. From

The Dome of the Rock in Jerusalem is located on a site sacred to Islam (as the spot where Muhammad ascended to heaven), Judaism (as the place Abraham prepared to sacrifice his son Isaac), and Christianity (as the place during the Byzantine Empire where Constantine's mother had a small church built).

observing how great stones were placed, as in Stonehenge in England or throughout Maya and Aztec cultures in Central and South America, scholars deduce that people observed the heavens for signs of divine will. They paid attention to the seasons of the year and the movement of sun and moon and stars, calculating some of their bearings from these. Many ancients worshiped sun-gods or moon-gods. Such observance has lived on in moderated ways within literate cultures, where Judaism, Christianity, and Islam, among others, thrived. Their sacred texts prescribed certain ceremonial days in the light of the phases of the moon.

Just as they looked up to the heavens, these religious folks also looked backward and ahead, as their texts reveal: they wanted to account for how the world

came into being and what its future, often a future ending in destruction, would be. Their stylized stories of beginnings (myths of origin) provided guidance for daily living. Their altars and relics also signal that they were concerned about weather and the gods or forces that control it, since it had so much impact on their survival and possible prosperity. They danced, prayed, and made offerings to deities associated with agriculture and hunting.

The Rise of “World Religions”

Knowledge of what religion meant in ancient lives becomes more sure when historians can deal with texts in which priests and scribes recorded their presumed transactions with the divine or in which they prescribed ceremonies. Many of those have left rich heritages where they appeared around the Mediterranean Sea and especially in the Middle East. In the fifth century BCE Athens was a bustling city, whose architects produced temples such as the Parthenon, where the statue of Athena by Phidias dominated. Readers of the literature of ancient Greece become familiar with large companies of gods, whom citizens always tried to understand, often to pacify, and sometimes to emulate.

While a thousand years before that, around 1500 BCE, Chinese peoples gave signs that they were preoccupied with the sacred, it was with the birth of Confucius in 551 BCE that texts appeared which provide access to the spiritual world of China. Whether Confucius should be thought of as a religious founder or a philosopher is a point of debate, but students of Chinese religion characteristically study his writings. These became influential in China and have remained so thousands of years later. He taught followers to be humble and generous, respectful of their ancestors, and devoted to civic life.

Even before Confucius died, China saw the emergence of another philosophy, a this-worldly faith, Daoism, which paid little attention to a life to come, as most other religions have done. Attractive especially to poor farmers, to peasant classes, it taught reverence for the natural world, the landscape, in the

face of which people were to learn to be serene but never weak.

More vital and influential through the centuries have been religions that emerged in the subcontinent of Asia, especially in India. Less interested in science and invention than the Chinese, Indians can be said to have specialized in responses to the sacred. Settlers of Indo-European background planted the roots of Hinduism, a faith that called for respect, even awe, for priests and holy people called Brahmins. It is hard to grasp an essence of Hinduism, so diverse are the shoots and so manifold are the sacred writings that grew from those roots. It called for worship of many gods including one above the others, Brahma. A core belief of Hindus was that all living beings possessed an inner soul, one that outlasted the body but would then transmigrate to a new body. That belief led to regard for cows as sacred. But Hinduism is not only a set of beliefs: it stipulates complex practices, many of them related to the belief in transmigration.

Just as Daoism coexisted with and challenged Confucianism in China, so Buddhism emerged to rival Hinduism in India. In the case of this philosophy and religion it is possible to point to a single founder, Siddhartha Gautama (566–486 BCE), son of a prince from Nepal. Sheltered in childhood and assured a life of leisure and reasonable luxury, he left behind the way of life these permitted and rode off seeking enlightenment and salvation. Indeed, he did experience such, and became known as “The Enlightened,” the Buddha. His journey led him and his followers to self-denial and the pursuit of sanctity. While Hinduism fostered a caste system in which the poor were destined to remain poor and the rich to enjoy riches, Buddhism was more spiritually democratic. But the wealthy were also attracted, and many of them contributed to the building of monasteries that were attractive to the most rigorous followers. Buddhist monasteries sprang up in city after city along the holy Ganges River.

Buddhism entered world history and was assured of a future when Asoka, a king of India, gained power and prestige often by the use of the sword but also

with building and humanitarian concerns, around 265 BCE. Through his spreading empire Buddhism prospered, while Asoka built hospitals and educational centers to give it practical effect among the people he dominated. Hinduism, after early prosperity, languished but was periodically revived. Buddhists meanwhile spread their self-disciplined ways of life into China and Japan, eventual and virtual home bases for one of what came to be called “the world religions.”

Developments Called “Greco-Roman,” Jewish, and Christian

Greek and Roman cultures survived in the centuries of great cultural productivity. Philosopher Karl Jaspers spoke of the centuries between 700 BCE to 200 BCE as an “axial period,” a time of religious formation and creativity, and these dates are commonly accepted. This is often marked in Greek drama and Roman poetry as well as in the records of statecraft. While honor was shown the old Greek gods in the course of developments associated with Rome in the fourth century BCE, the Roman rulers increasingly came to be treated as divine agents worthy of worship. They, in turn, invoked some of the gods, offering them sacrifice of animals. Culturally open to other influences, they also welcomed Isis, the mother-god from Egypt, who ruled the universe, and Mithras, the sun-god from Persia. Much more complex was the arrival of Jews from Palestine and, from within their Judaism, a new sect that the Romans soon learned to name “Christian.”

The Roman Republic came to be the Roman Empire in the centuries in which Judaism and Christianity came to be a presence. Together these two also became “world religions,” dynamic inheritances from a five-hundred-year period in world history that saw special creativity and devotion. Webbed at the beginning and conflicted by the end of the first century CE, Judaism and Christianity also demand separate treatment by scholars of religion.

Hebrew people—their name refers to their having wandered—told themselves that they were people who came from slavery in Egypt. They had

To one who has faith, no explanation is necessary. To one without faith, no explanation is possible. • **Saint. Thomas Aquinas (1225–1274)**

seen glories, beginning with their conquest of many small ethnic groups in Palestine, and kingship beginning around 1000 BCE. They revered the memory of charismatic rulers such as David, who captured his capital city of Jerusalem, and then his son Solomon, a temple-builder there. The temple-goers and their priests and scribes recounted and lived by stories of their freedom from slavery, their wandering in a wilderness, and their conquest in Canaan, on the soil of Palestine.

Among their stories, one that inspired much of their moral concern and many of their religious rites was one about Moses, a leader who helped free them from slavery, often with apparently miraculous means. Among these was one that had to do with the deity they called Yahweh, revealed through ten “utterances” that came to be called the Ten Commandments. Followers of these commandments, in northern and southern kingdoms (the latter being called Judea, hence “Jewish”), considered to be the special chosen people of God, forbade the making of divine images. They often revered lesser gods whom they considered anti-Yahweh, but to whom they were frequently attracted. Their attraction quickened criticism by prophets, mainly in the eighth century BCE. These were men in a special calling that directed them to judge errant people and promise divine assurance to the righteous. God held Jews to an especially high standard, and, as they interpreted it, let them prosper or meet disaster, depending upon how well they kept divine laws, especially the Ten Commandments.

While most Jews, freed from captivity in Babylon after 586 BCE, lived in Palestine, they also saw the creation of the Diaspora, a dispersal of peoples, and they were strategically placed in much of what had become the Roman Empire. They built synagogues and worshiped in relative freedom so long as they did not give the rulers any troubles. It was Christianity, one of Judaism’s offspring, originally a Jewish sect, that did give trouble and receive it.

This faith centered in a rabbi of Nazareth, Jesus, in the course of time believed by most of his followers to have been born of a virgin, Mary of Nazareth, who had been impregnated by the Holy Spirit, and without

a human father. He was one of many latter-day prophets, such as John the Baptist, who influenced his mission. In the sacred writings called the Gospels, which became part of a “New Testament,” this Jesus was portrayed as a wonder-worker whose main task was healing and preaching the imminence of God’s kingdom. Exactly what that meant depended upon who was writing about it or interpreting the writings, but it had to do with divine sovereignty exercised in “saving” people from their sins.

With Israel chafing under resented Roman rule, however, many wanted saving from the Romans. The Gospels picture Jesus teaching his disciples that he was to be executed. Meanwhile, a growing number of enemies among religious authorities targeted him for execution. The Gospels portray him as knowing that this form of execution, crucifixion, was to be his destiny, his means of saving people. In such portrayals his death was a sacrifice pleasing to the one he called Father. In the experience and belief of his followers, he was resurrected, raised from the dead, and after making appearances among them for forty days, ascended into heaven, thence to rule.

In the eyes of Greeks and Romans the sect that followed this resurrected one, called Christians, could have survived as one more strange movement. However, while some of them served in the Roman army and paid taxes, they refused to give signals of worship that would show they regarded the ruler, Caesar, as divine. Forty years after Jesus’ death, around 70 CE, conflicts between these Christians and other Jews led to schism and growing enmity. More important for survival, however, was the attitude of Roman rulers and other elites, who scorned them and saw them as subversive. Before the year 70, persecution of Christians had begun in Jerusalem, Rome, and outposts along the way this fast-spreading faith was developing.

Divided Christendom and the Rise of Islam

In the course of three centuries as Rome declined, one of its emperors, Constantine, for a mixture of reasons, became a believer and directed his empire on a course

that led Christianity by the end of the fourth century CE to be the official religion of Rome. The persecuted now became the persecutors in many instances. Christianity was official, legally established, and was to remain so for a millennium and more. When as the eastern half gained power and influence and Rome divided, the Christian movement also progressively divided, with headquarters in Rome and in Constantinople, Constantine's power became based in what is today's Turkey. The Christian story, including the account of the development of its creeds, doctrines, and practices, henceforth had western and eastern versions, and these split permanently in 1054 CE.

If Christianity sprang out of Judaism, still another world religion, second in size only to Christianity, developed out of and then over against those two. It developed in the small cities of the Arabian Peninsula, where Muhammad was born around 570 CE. Christians and Jews lived there, but old religions considered to be pagan thrived in the interior, where at Mecca, Muhammad's birthplace, people revered and made pilgrimages to a great black meteorite in a shrine they called Kaaba. In that city Muhammad experienced a profound religious revelation and claimed that he was recording the direct utterances of God, Allah, in the sacred book that became the Qur'an. Islam means "submission," and the religion that issued from the prophet Muhammad's revelation and transcription, stressing obedience to Allah, prescribed precise and simple ways in which one pursued Islamic faithfulness.

While the Qur'an included many passages advocating tolerance and peace, the text also included militant themes and the prophet's career included military ventures. The Arabian Peninsula, always dry, in the early years of the sixth century was experiencing drought, and many desperate Arabs joined Muhammad's conquering armies. By 635, Damascus in Syria fell, followed the year later by Jerusalem. The armies invaded Egypt and captured Alexandria in 641. Everywhere the victorious Muslims won converts and built mosques. Many of these moves were threatening and even devastating to Christians, who met defeat in northern Africa and parts of Europe, including Spain. There Muslims developed a sophisticated civilization,

A highly decorated Hindu processional cart in India.

which it shared with Jews and Christians until 1492. Constantinople had fallen in 1453, and for much of the next century the Ottoman Turks spread Islam while assaulting Europe all the way into Hungary. The Christians earlier gained some selective victories as they tried to win back the holy places of Palestine in a series of bloody crusades, but outside Europe itself Islam held its own and became a permanent challenger.

Religious Expansion and Division

Meanwhile, for a thousand years Buddhists were on the move. They came from India into many parts of China, just as they had expanded into Sri Lanka. Mahayana, a new form of Buddhism, developed in northern India. It was a more aggressive and proselytizing faith than the passive Buddhism of earlier years. Shrines and giant statues of Buddha marked the path of their progress. Emperor Shomu in Japan embraced Buddhism in 737. Spared in an epidemic, he credited

This small Catholic chapel in New Mexico, El Santoria de Chimayo, was built by Spanish settlers and now is a pilgrimage site for people seeking cures.

Buddha and erected the Great Buddha at Nara. Like Christianity and Islam, Buddhism spread not only with armies but also through energetic missionaries and proselytizers. Each left in its trail and on its soil great houses of worship and thousands of smaller ones, places for pilgrimage and devotion, libraries for the encouragement of learning and piety—in short: civilizations.

While Western Catholic Christianity that was centered in Rome dominated Europe, with the Muslim present in the West, in Spain, and threatening in the East toward Vienna, and with Jews surviving as an often sequestered minority, one church system set the terms for religious and much of civil life. The Catholic Church was in position to enforce loyalty and persecute dissenters. The head of Catholicism, the pope, could not only field an army but also demand and frequently gain obedience from monarchs whose people

would be denied access to heaven if their rulers did not acquiesce to Rome.

It was in that context that all over Europe restless reformers began to question the Catholic system and to subvert it. Their main instrument was the preached and taught Bible, a book of divine revelation that became available in the fifteenth century CE as Johannes Gutenberg's invention of movable type and new presses helped ordinary people gain access to it and its message. In German-speaking Saxony a monk, Martin Luther, after 1517 preached a gospel of liberation and came to storm the official church, which hounded him in turn. Joined by Swiss and other reforming scholars and with support of some princes in the Holy Roman Empire (much of today's Germany) and elsewhere, these questioners undercut the teachings and much of the edifice of Catholicism, though it continued to dominate in most of Europe. But as the new movements called Protestant after 1529 made their way, often in alliance with the state in Germany, England, Scandinavia, the Lowlands, and elsewhere, they helped assure that Europe would be divided religiously. This became doubly evident as Protestants themselves were divided, in no position to be attracted back to Rome as a unit or to be destroyed as one.

When the Western Hemisphere became a subject of knowledge in Europe, Catholic Christianity prevailed in the central and southern Americas. Meanwhile, Dutch, Swedish, and especially English churches had turned Protestant. Merchants and explorers from these countries dominated in that part of America that became the United States, as well as in all of Canada but Quebec.

Renaissance, Enlightenment, and Secularism

While the faith was spreading, Christianity and to a lesser extent all religions in the sixteenth century began to face fresh challenges from propagators of a new approach to the world. Sometimes it was called the Renaissance, because it involved a recovery in the thought world of the glories of Greece and Rome, just

The god of the cannibals will be a cannibal, of the crusaders a crusader, and of the merchants a merchant. • **Ralph Waldo Emerson (1803–1882)**

as it celebrated their arts and sciences. Sometimes the change came in what was called the Enlightenment. This was a movement in northwest Europe, one that celebrated reason, progress, and science, often at the expense of faith.

In Renaissance times some challengers such as Copernicus and Galileo, who presented new views of the physical universe, were harassed, the latter condemned by the pope. Sometimes they won converts from enlightened church leaders who fused rationalist or scientific thought with their faith and church. But in any case, the modern world saw an increase in tension between believers and nonbelievers. The emergent worldview of the latter came to be called “secular,” from the Latin word *saeculum*. The implication or even overt claim was that whether or not God existed, one could live out a full life interpreting and changing the world without recourse to God, sacred texts, religious institutions, and the like.

In the nineteenth century, on the soil of secularism, there arose more pitiless and belligerent rivals to Judaism, Christianity, Islam, Buddhism, and Hinduism. Most of the twentieth-century forms ended in -ism: Fascism, Communism, Nazism, Maoism were typical. Many of these took on the trappings of the religions they set out to replace. They called for the sacrifice of millions of lives in war, and they took other lives. They generated myths of leadership and symbols such as the swastika, the hammer and sickle, and the star to rally or subjugate people. They invented ceremonies and rituals. In due course their creations imploded and they waned, while in most cases the religions they had set out to abolish returned and often prevailed in various areas.

Religious Survival and Revival

In the twenty-first century, religion without doubt plays as large a role as it had centuries earlier, despite many predictions that modernity, secularity, and science would sweep it away. The old heartland of Christianity, western Europe, did not experience the growth in the number of religious adherents, though

Christianity in its various forms survived there. Yet nearly 2 billion people around the world were numbered as Christian in 2009, about one billion of them Roman Catholic. Notably prosperous were new Christian movements, especially Pentecostalism, in the southern world, especially sub-Saharan Africa. Meanwhile Islam advanced by population growth, efforts to convert, and development of philosophies and movements attractive to many among the world's poor. Hinduism was also among the advancing religions.

Religion came wearing many guises. In a vast generalization that needs many qualifiers, it could be said that in the world of today, more people are being healed *and* more are being killed in the name of religion than of any other force. Healing here would mean not only physical and personal spiritual healing, but reconciliation, concord, works of justice and mercy. Killing here need not always mean literal murder; it could imply anything negative related to persons, including oppression, repression, suppression. But it can point directly to killing, since armies move against each other, or terrorists act in the name of their gods. Efforts at reconciling the religious do occur, and many people of good will in many cultures initiate and promote movements of interfaith dialogue and common action. These are dwarfed, however, by the massive, convulsive moments of tribe against tribe, people against people, and often nation against nation on the basis of mixed motives, but many of them being religious.

Religion in the Contemporary World

Any assessment of the role of religion has to begin with the place it plays in the life of individuals. This is as true in Jainism, Sikhism, Shinto, Babism, and other significant movements that one will find in atlases and encyclopedias of religion or in open encounters around the world. Historical change came because of Buddha realizing enlightenment, Jesus teaching and dying, monks like Francis of Assisi, Jewish scholars like Maimonides, and reformers like Martin Luther experiencing fire in their soul, acquiring a mission,

and then spreading their message and changing the world. But there would be no religious movements were there not also stirrings and hungers in individual souls, and at least partial and often wholly enthusiastic responses to God or the gods.

At the other extreme, religions have to be appraised as mass movements. Millions of Muslims make pilgrimages to Kaaba in Mecca, as Christians went on crusades; they form armies in support of kings who they think rule by divine right, or they stimulate revivals, awakenings, and renewal movements. They can be attached to movements already existing: often nations are ready to war against nations, but they mobilize when they are convinced that God or the good is on their side, and that enemies of God—Satan, if you will, among others—are on the other side.

Religions often undertake revolutionary missions. While their main function may be conservative, urging respect as they often do for the wisdom and achievements of sacred ancestors and offering ballast and sanity in times of disturbance, they may also take it to be their mission to upset the world. Thus the Hebrew prophets of the eighth century BCE, acting on the basis of a covenant they claimed God had with Israel that was now being forgotten, called the people to repent, change their ways, and do works of justice and mercy. They may form resistance movements against modern dictators, or provide conscience for individuals who need courage and divine authorization. So religions make history both in their integrating roles and when they are prophetic and disruptive. Since they deal with invisibles, with soul and spirit and unseen forces, they may not be as easy to track and chronicle as are wars, earthquakes, famines, or catastrophes, but they do as much as such phenomena to alter the human landscape through history and into the present.

Religious Freedom

Religious freedom did not emerge in world history as a widely accepted idea until the modern era. Governments generally mandated religious belief on the assumption that a common religion is essential to social stability. This assumption has not died easily, and still prevails in some areas of the world. Nevertheless, religious freedom has now become an almost universally accepted norm, backed by international law and the constitutions of most nations.

Religious freedom can be defined as the liberty, guaranteed by a state authority to its people, to believe (in matters concerning religion) that which is dictated by conscience, including no belief at all. The concept is relatively new in world history because governments since the earliest times adopted religions as a means of fostering stable and unified societies.

Ancient Societies

In ancient societies there was no differentiation between the religious and the secular. All of life was religious, and state authority generally assumed the role of moral agent and mandated religious belief to further its own ends. Ancient Mesopotamia, Egypt, and Greece were polytheistic cultures in which civil authorities were also considered either priests or gods themselves, and the religious life of subjects was closely regulated. As popular new religions emerged, state machinery frequently adopted these religions as a basis of unity for society. Thus Hinduism in India, Buddhism in Thailand, Shintoism in Japan, Confucianism and Daoism in China, Judaism in Israel, and

Islam in the Middle East all influenced law and public policy and still retain today a status as formal or semiformal state religions. In these settings, freedom and religion have not been natural allies. The brave heretic who has pursued religious ideas outside those of official sanctions has frequently been persecuted or even executed.

The Union of Church and State in Medieval Europe

This pattern of persecuting heretics persisted in the early Roman Empire. Under emperors such as Nero, Trajan, Decius, Valerian, and Diocletian, Christians were sometimes executed for violating the mandatory worship requirements of the empire. But Christianity continued to grow, and by the fourth century claimed as much as 10 percent of the Roman population. The persecutions against the Christians ended, however, only when Constantine became the first emperor to become a Christian. He was instrumental in the passage of the Edict of Milan in 313, a document of landmark proportions in the history of religious freedom. It provided “that liberty of worship shall not be denied to any, but that the mind and will of every individual shall be free to manage divine affairs according to his own choice” (Pfeffer 1967, 13). The edict elevated Christianity to a status equal to that of other religions in the empire, although within a decade Constantine altered laws to give legal preference to Christianity. The Roman state built great Christian edifices, instituted Christian holidays, granted exemptions from taxation to Christian clergy, and persecuted adherents of “heathen” religions. The persecuted had become the persecutor. In 380, under Emperor Theodosius,

In an act of defiance, John Endicott, a follower of Roger Williams and passionate supporter of religious freedom in colonial New England, cuts the cross from the King's banner.

Christianity was officially enshrined as the state religion of the empire.

The Christian state became the model for all of Europe during the Middle Ages. The Orthodox Church became the established religion over much of the Eastern Roman Empire, including Greece and Russia; Catholicism prevailed in the West. The goal of the church–state partnership was the glory of God and the salvation of man. Any impediments to this goal were dealt with harshly. Thus by the thirteenth century, Western authorities devised a formal Inquisition by which heretics would be systematically sought out and, if deemed beyond rehabilitation, executed. Between 1231, when the Inquisition was formally instituted by Pope Gregory IX, until 1834, when the Spanish Inquisition was finally abolished, tens of thousands of heretics were burned at the stake because their faith did not match the officially approved Christian doctrines. Religious freedom, obviously, was not part of the medieval vocabulary.

Occasionally there emerged, however, from within the Christian Church, voices in behalf of religious freedom. Tertullian, Justin Martyr, Hilary of Poitiers, Chrysostom, and Augustine, among others, pleaded the cause of toleration and condemned punishment of heresy. In the early third century, for example, the lawyer-cleric Tertullian wrote, “it is a fundamental human right, a privilege of nature, that every man should worship according to his own convictions. One man’s religion neither helps nor harms another man” (Pfeffer 1967, 15). In the late fourth century,

Augustine similarly defended toleration of unorthodox religious views. Later, however, when members of the Donatist sect engaged in acts of civil disobedience, he apparently changed his view and opined that compulsion was benevolent, “for what is a worse killer of the soul than freedom to err” (Pfeffer 1967, 16). Due to the weighty influence of the brilliant Augustine, one scholar had articulated what has become an accepted estimation of him. Because of Augustine, he wrote, “the Medieval Church was intolerant, was the source and author of persecution, justified and defended the most violent measures which could be taken against those who differed from it” (Pfeffer 1967, 16). Some have said that Augustine’s views became the “charter for the Inquisition.”

The Crusades

Equally out of step with the spirit of religious freedom were the crusades of the eleventh, twelfth, and thirteenth centuries. The purpose of the seven crusades, initiated by Pope Urban II in 1095, was to recapture the Holy Land that had been lost to the Muslims and to extend the rule of Christianity in the “land of Christ.” The motto of the crusades became “Kill the infidels.” In carrying out the slaughter of tens of thousands of Muslims, the crusaders availed themselves of the opportunity to root out Jewish and Orthodox infidels as well. The popular Peter of Cluny asked, “Why wait for the infidels in the Holy Land? We have infidels here—the Jews” (Wood 1966, 9). It

A plaque mounted on the wall of a Protestant church in Provence, France, recounts the Protestant fight for religious rights in this mainly Roman Catholic region.

has been estimated that in the First Crusade alone thousands of Jews across Europe were massacred. Pope Innocent III, perhaps the greatest exemplar of militant Christianity, launched the Fourth Crusade in 1202. While en route to the Holy Land, his army of twenty thousand crusaders sacked and destroyed the great Orthodox city of Constantinople, slaughtering thousands of citizens, burning much of the city, and destroying more of the city's great religious treasures than were lost when the Turks later bludgeoned and captured the city in 1453.

Religious Intolerance during the Reformation

The Roman Catholic Inquisition of the fifteenth and sixteenth centuries unleashed fresh attacks against a rising number of Protestants. Protestants in turn persecuted Catholics as well as competing Protestants. Contrary to popular belief, the

Protestant Reformation did not usher in a new era of religious freedom. In fact, the rise of Protestantism witnessed a fresh outbreak of religious intolerance. Protestants were vigorous in winning converts from Catholicism, but they were often as vicious in their persecution of Catholic and Protestant heretics as Catholics had been against them. The leading lights of the Reformation, Martin Luther and John Calvin, were never reluctant to exterminate their own adversaries. Luther frequently recommended to the Duke of Saxony the execution of Catholic, Jewish, and Anabaptist heretics. Calvin himself prescribed the execution of numerous heretics, including the Unitarian Michael Servetus at Geneva in 1553. Calvin's contemporary and Protestant scholar Sebastian Costello probably had it right when he wrote of Calvin, "If Calvin ever wrote anything in favor of religious liberty, it was a typographical error" (Wood 1966, 11).

The spread of new religious ideas across Europe during the Reformation led to a series of religious wars that was finally curtailed only by the Peace of Westphalia settlement of 1648. By then, it was apparent to many that religious tolerance was essential, lest everyone in Europe die of heresy. A healthy spirit of tolerance appeared in many dissenting groups, most notably the Socinians, Anabaptists, Diggers, Quakers, Politiques, and Baptists. These groups, all of whom experienced acute degrees of religious intolerance, were far apart on theological matters but united in their advocacy of religious freedom.

The growth of religious tolerance was not merely a matter of expediency, however. Seminal thinkers such as Hugo Grotius, Henry Parker, Thomas Hobbes, John Locke, Jean-Jacques Rousseau, Sidney Algernon, John Milton, Erasmus, Voltaire, Thomas More, and Dirck Coornhert all protested the mania of the times—"hereticide"—and took up their pens to propose new political and theological bases for religious freedom. Locke in particular was instrumental in proposing the notion of the secular state, which removed jurisdiction over religious matters from civil authority, thereby protecting each

This drawing depicts the massacre of Mormons at their camp at Haughn's Mill, Illinois, in 1838. The Mormons were subjected to nearly seventy years of government-backed oppression in the 1800s.

individual from state-mandated religious conformity. He articulated a theory of natural rights that placed fundamental rights of life, liberty (including religious freedom), and property beyond the reach of government.

Religious Freedom in America and Elsewhere

These ideas took root as nowhere else in America. Roger Williams, who founded the colony of Rhode Island, fought an ideological war against theocratic traditionalists in Puritan New England. Williams set up a secular state and welcomed to his colony settlers of every religious persuasion, requiring only that they conform to standards of good citizenship. His policies led Puritans and others to refer to Rhode Island as “that sewer,” but his ideas eventually found their way into the U.S. Constitution in the late eighteenth century.

The new Constitution and its Bill of Rights guaranteed religious freedom and ensured it with an establishment clause that prevents government from establishing any religion or even from preferring

some religions over others. The United States was the first nation in human history to formally adopt the principle of the separation of church and state as a fundamental element of its public philosophy. It was a noble experiment in the founding era and remains so today. The experiment was undertaken by the framers in the hope that it would enable America to escape the persecutions and religious wars that had characterized the Christian West for almost two millennia. Due to the success of this formula in America, other nations have since adopted the idea of church-state separation as a guarantor of religious freedom, and today, approximately one-half of the nations of the world make formal guarantees of church-state separation in their constitutions.

Internationalization of Religious Freedom

The twentieth century witnessed unprecedented progress toward the internationalization of religious freedom. Of the three major international documents that universalized the principle of religious freedom

in the twentieth century, by far the most central is the Universal Declaration of Human Rights, passed by the United Nations in 1948. This landmark document declares that “Everyone has the right to freedom of thought, conscience and religion; this right includes freedom to change his religion or belief, and freedom, either alone or in community with others and in public or private, to manifest his religion or belief in teaching, practice, worship and observance” (Claude and Weston 1992, 421).

The declaration embraces modernity’s political principle that one of human government’s main roles is to protect people’s religious choices, not to mandate religious conformity. It took centuries, even millennia, of religious wars and government-perpetrated religious persecution for the majority of modern nation-states to come to this position, but the principle is now widely accepted, especially in the West, and its near universal recognition in the 1948 declaration is undoubtedly a human milestone.

Whereas the declaration imposed a *moral* obligation upon all signatory nations, later documents went further in creating a *legal* obligation to comply with its broad principles. The International Covenant on Civil and Political Rights (1966), ratified already by approximately 150 nations, prohibits religious discrimination “without distinction of any kind, such as race, colour, sex, language, political or other opinion, national or social origin, property, birth or other status” (Claude and Weston 1992, 432). Moreover, the 1966 covenant provides a broad definition of religion that encompasses both theistic and nontheistic religions as well as rare and virtually unknown faiths. The covenant is especially important because its provisions are mandatory for the states that have ratified it.

Finally, the United Nations Declaration on the Elimination of All Forms of Intolerance and of Discrimination Based on Religious Belief, enacted in 1981, is a fundamentally important document protecting religious rights. The declaration includes the most comprehensive list of rights to freedom of thought, conscience, and religion enumerated in any international instrument.

Human civilization has achieved much over the last three thousand years in making religious freedom a fundamental human right. Much remains to be done, however, to make religious freedom a reality for all peoples of the world. There is no more important project to be undertaken by the human community now and in the future.

Religious Fundamentalism

Lexicographers in the 1920s narrowly defined fundamentalism to describe movements in American Protestant denominations that were devoted to biblical literalism. The term has been widely applied in a broader sense (often contentiously) to other religious movements or sects worldwide. Some scholars see the term as stigmatizing or unfairly lumping groups together, while others recognize its value as a “genus” that can foster comparative analyses among groups it comprises.

Religious fundamentalism, often confused with conservatism or traditionalism, is a name for a movement in any religion that retrieves “fundamental” elements of that religion and projects them into new formulations in reaction to challenges from modernity, however that is defined. This reaction may lead to protective withdrawal by groups in some cases, at least in early stages. In practice, however, leaders of such movements attract followers to engage in militant action against whatever it is they regard as a profanation or whatever stands in the way of their battles for their God. Since fundamentalisms appear in Protestant Christianity, Judaism, Hinduism, and Islam, they can be seen as both local and global assaults on both secular and settled religious orders, be they conservative or liberal.

Problems with the Word “Fundamentalism”

Scholars agree that the first use of the term occurred in American Protestantism early in the twentieth

century. Some question, therefore, whether the word might fairly, and without causing confusion, be used to characterize forces in other religions. On the side of the critics are factors such as these: it seems unfair and perhaps imperial to borrow from an American domestic movement a term to impose on other religious movements that draw on vastly different sources. Second, the term is often seen as pejorative, stigmatizing. In addition to that, it does not always have a cognate term in the languages identified with other religions. Fourth, it may license comparisons that unfairly lump together disparate movements that lose their identity when so classified.

Over against these, defenders of the usage recognize that the term is simply established, in textbooks and media, in statecraft and scholarship, and argue that efforts are better aimed at clarifying the term than trying to abolish it. In addition, they point out that similar categories of words travel from language to language, situation to situation. Words like colonialism, revolution, conservatism, nationalism, and others are all “born” somewhere in the West and travel to other settings and languages. Third, fundamentalism is a genus, and scholars or communicators can clarify issues by pointing to species: the Islamic fundamentalism of the Wahhabi movement might have formal congruence with the Jewish fundamentalism of Gush Emunim or a party of Protestants in Northern Ireland, but the content of their claims differs vastly. Finally, no other term has come forward to foster comparative analysis. Thus “Islamist” works only for Islamic movements. And comparisons are valuable, since only by isolating them do certain features stand out.

Features of the Fundamentalist Movements

The word “fundamentalism,” in religious contexts at least, is not to be found in any dictionaries published before the 1920s. When Baptist Protestants in the United States during intradenominational struggles in the early 1920s coined it, and when Presbyterians took it up, lexicographers had to take note of it and defined it as a Protestant movement devoted to biblical literalism. What they may not have noticed is that in the same decades such movements were developing in India in what have become major political parties, or in Egypt under the Muslim Brotherhood, from which fundamentalisms spread to Saudi Arabia, Iran, and the larger Islamic world.

World historians have it as their mission to account for the long record of movements, and ask about the distant origins of fundamentalism. But students of the movements will find that they rose as reactions to modernity, again “however defined.” Definitions may, for instance, take into account critical assaults on sacred canons, such as the Bible or the Qur’an. When conservatives perceive these as assaults from within their religious camp, they feel they must react and respond. Thus Muslim fundamentalists from the 1920s to the 1990s almost always directed their fire to what they perceived, not always inaccurately, to be corrupt and repressive but only nominally Muslim governments. American Protestant fundamentalists did not have the old enemy of Protestantism, Catholicism, as an object of attack so much as rival groups that were religiously “closer to home.” They attacked their fellow Presbyterians or Baptists for treason to their own cause. The critical movements that inspired the responses developed just before the twentieth century or early in it, so one could not have located and defined fundamentalism without this modern assault.

Just as often, the reactive response may be against perceived threats to one’s domain. Thus “Westerners” as “infidels” were seen to be subverting Iran in the 1970s, thus evoking purifying countermovements by the followers of the Shi’a Ayatollah Khomeini.

Fundamentalists in the United States felt called to oppose liberal Protestants allied with secular humanists and others who were critical of cherished practices such as issuing prayers in public schools while these critics provided theological justifications for disapproving moral expressions, for example, the legalizing of abortions. In Israel, if there seemed to be even a trace of conciliation by peace-seeking governmental administrations, movements like Gush Emunim (Bloc of the Faithful) organized, demonstrated, and built not-yet-approved settlements on the West Bank.

To pursue their aggressive missions in the name of God, fundamentalist movements must build at least figurative boundaries around their movements. They may not keep outsiders or compromisers at a physical distance, as sectarians were able to do before the rise of mass media, mass higher education, and global commerce. But they can develop their own media of communication, their own separatist institutions, their own sets of stigmas with which to label the moderates or other deviators. In media especially, their difference from conservatives or traditionalists is most apparent: they embrace the very modern instruments of communication—tapes, videos, radios, films, the Internet—that were agents of assaults against them. They fight modernity with modern technology.

Their spiritual weapons need ammunition. They all find it in shared sacred texts, usually from centuries before, from times that they perceive to have been perfect or that offered prototypes for living in a perfected world. From these they select the elements that will most help them fight off modernity; these become “the fundamentals.” They need strategies, which can range all the way from attempts at boycotting or demonstrating, from efforts at amending constitutions to revolution and warfare—and, in the end, in some cases, terrorism in the name of God. With these self-confident moves, which they experience or claim to be God-guided, they are certain about where history is going, however long it takes.

Fundamentalisms have to be efficient; what are called “free riders” and others who are only half-committed are unwelcome. Participants have to be ready for total sacrifice of self. So they will pursue

most zealously the group members they perceive as compromisers, people who should know better but who are too ready to barter too much away. Thus an American Protestant fundamentalist chronicler named the evangelist Billy Graham the most dangerous American of the last century—because, he claimed, Graham knew better than to appear on platforms with others who do not share all details of fundamentalist faith.

Finally, fundamentalists need all-or-nothing ideologies. Scholars speak of these as “Manichaeism,” after a dualistic religious movement: dark opposes light, with no shadows between them; it is God versus Satan, Christ versus Antichrist, Allah versus the infidels. There is no room for ambiguity or compromise in the minds of individuals or in the approach of the group as a whole.

Still problematic to the student of world history is the claim that since the movements developed in reaction to modernity, including the experience of religious pluralism and the often accompanying tendency to relativize “truth,” is it not true that many religious movements had to fight off their own “modernities” long ago? Thus New England Puritans abhorred the very idea of “innovation,” and promoted the old ways. If this is the case, would not one have to begin the story of any modern religious fundamentalism by looking at precedents and antecedents through history? Thus Hindus and Muslims have had to fight off modernisms in many generations. Protestant fundamentalists bear some resemblances to Anabaptist or sectarian movements of the sixteenth and seventeenth centuries. So what is new?

The Place of Fundamentalisms

American Protestant fundamentalism, for one instance, fights its battles in the context of a republic where political means are accessible. Resorting to violence is extremely rare. Exceptions such as the bombing of abortion clinics by radical fundamentalists are criticized by mainstream fundamentalists, who find their movements set back by such violence. They may express resentment against a modern world that they

believe is depriving them of their rightful place. After that, their energies go into political organization, attempting to persuade voters, to gain power with holders of office, to employ mass media to make their case.

In the United States it is hard to remain a “pure” fundamentalist. To gain anything in a republic a movement must enter into coalitions, make alliances, swallow some principle for a common cause. Or one may turn to more moderate movements that are religiously satisfying in respect to message though less attractive in their cultural roles. Fundamentalists have been in the public eye since the Scopes trial, a battle over evolution in public schools in 1925. Many people on all sides have been nettled, unsettled, angered, frightened lest their cause be defeated, but they have not had to fear guns.

In Israel one of the very rare fundamentalist movements was Gush Emunim. It was a very modern force, organized under charismatic rabbis who agitated in America and in Israel especially against Israeli leaders who even entertained the idea of coming to terms with the Palestinians. Many in this “Bloc of the Faithful” were offspring of barely observant Jews who in their new turn “went all the way” into and beyond Orthodoxy. Members make claims that they are relying on ancient sacred texts in which the land of Israel was given, with stipulated and precise boundaries, to the people of Israel, the Jews. They find support from and kinship with American Protestant fundamentalists and their slightly more moderate kin who read biblical passages “fundamentalistically” in order to certify and sustain their support of Israel.

In India, the Rashtriya Swayamsevak Sangh (RSS) organized what many Hindus call a cultural, not a religious institution. Maharashtrian Brahmins developed it within Hinduism and it became a base for militant opposition to equally militant Muslims. The two hard-line groups fought over sites that were holy to both. The RSS is an ideology of the Hindu nation. Keshav Baliram Hedgewar, founder of the movement, now a party, wanted to purge India of non-Hindu influences. It is highly organized in order to stimulate emotional response to Hindu appeals and to stand off

the Muslims. Many Indians welcome talk of a Hindu nation, but memories of the assassination of Mohandas Gandhi by RSS people makes them uneasy. And the RSS did teach people to use Western instruments, including weaponry. The RSS literature suggests a sense of embattledness, but the leaders have taught ordinary members to take out their rage on Muslims, who crowd what they think of as uniquely Hindu holy places.

The Muslim Brotherhood was founded in Egypt under the leadership of Hasan al-Banna' (1906–1949), a moralist who was repulsed by moral and spiritual corruption in Egypt and wanted to use the resources of Islam to counter it. The Brotherhood organized schools and hospitals, and became a very vocal critic of semisecular or nominally Muslim governments there. Most influential in the Brotherhood was Sayyid Qutb (1906–1966), a former secularist who turned to be a zealous Sunni Muslim leader. He abhorred what he saw in the United States, which looked corrupt, sensual, immoral, and godless. Qutb was executed by the Egyptian government for his subversion, but his version of Wahhabi Islam thrived, especially in Saudi Arabia. It is out of this tradition that the al-Qaeda movement emerged.

Best known to the West has been the Iranian revolution of 1979. It serves as a model of how fundamentalist movements make their way. The United States-backed Shah of Iran presided over a corrupt regime. As population grew and needed resources were not available to all but the upper classes, resentment developed among young urban males. So did aspiration and hope. After the shah fell, the exiled Ayatollah Khomeini came back from Paris to reoccupy the land that his followers felt had been immorally taken over from them. Soon the shah had to flee, the Khomeini faction grew in power and threat, the United States retreated, and a new pattern of militant, revolutionary unrest followed. Whether they are called fundamentalist or not, movements like the RSS and the Muslim Brotherhood illustrate how the forces develop.

They begin as conservative or traditionalist complexes. They are oppressed (not all fundamentalists

are literally poor, though many are desperately so). Their enemy is seen as a corrupt betrayer of the tradition they believe is theirs. No matter what the world thinks, they must act. Allah will bless them now or, more likely, in eternity. And they will have made a contribution to purifying and ennobling an often corrupt and repressive regime. Something similar goes on in fundamentalist movements elsewhere, and in different religions.

As for the future, militant fundamentalisms are likely to continue to create upheavals of a sort unanticipated at the end of the Cold War. They resort to terrorism or destabilize regimes. At the same time, others run their course and settle for somewhat moderated expressions. In almost every major religious complex—Christian, Muslim, Jewish, Hindu, and the like—nonviolent fundamentalists will seek to make their way through efforts to convert others, to out-vote them, or to influence public policy through means and toward ends that they find satisfying. And “modernism” in its many forms, including with its manifestations of pluralism and relativism will remain the enemy.

Religious Syncretism

Syncretism is the attempt to reconcile disparate—and sometimes opposed—beliefs and practices. It represents a blending of schools of thought and is often associated with establishing analogies between two or more discrete and/or formerly separate traditions. Most studies of syncretism focus on the blending of religion and myths from different cultures.

Syncretism, in its attempt to reconcile disparate beliefs and practices, can be seen from positive and negative perspectives. Viewed positively, syncretism seeks underlying unity in what appears to be multiplicity and diversity. It is common in many aspects of society and culture, including language, literature, music, the arts, technology, politics, social organization and kinship, and economics. Robert D. Baird asserted that the term syncretism contributes little to our understanding of world religions since what it seeks to describe is nearly universal. He suggested that the term “syncretism” should be replaced by the term “synthesis.” Other scholars—most notably the anthropologist Richard Werbner—have suggested that anthropologists restrict their use of the term to the study of religions. Werbner has since rescinded his position. Still other social scientists—notably Peter Beyer and Jonathan Friedman—have suggested that the term syncretism may prove extremely useful for understanding many aspects of culture and society, including social organization, material culture, and processes of localization and globalization.

Viewed negatively, syncretism is a contentious concept that has undergone many transformations. To religious leaders, syncretism often implies impurity

and/or contamination and is associated with—but is not identical to—“eclecticism.” It is unlikely that any contemporary scholar or theologian would argue that processes of syncretism do not exist. Disagreements center on the word itself and on the history of its applications.

Classical Greek and Roman Concepts of Syncretism

The Ancient Greek prefix *syn-* means “with” and the word *krasis* means “mixture.” Thus, the term *synkhrasis* meant “a mixture or compound.” The Greek words *synkretismos* and *synkretizein* do not appear in classical literature until the time of Plutarch (c. 46–after 119 CE). Plutarch utilized a political meaning of the term in an essay entitled “On Brotherly Love” (*Peri philadelphias*), which appeared as a chapter in his *Moralia*. In searching for the origin for the word “syncretism,” Plutarch claimed to have found an example of syncretism in the Cretans who reconciled their differences and came together in an alliance whenever they were faced with an external threat. He labeled this coming together as “their so-called syncretism.” Plutarch’s use of the term later gave rise to negative connotations—many of which were never intended by Plutarch. For Plutarch, syncretism was not only a testament to political expediency, but also had potential to foster sociability and brotherly love. On the other hand, he also saw it as the root of insincerity and impurity. It became synonymous with a lack of authenticity. Passages from Plutarch’s *Moralia* attest that the term “syncretism” was known in the first century CE. Unfortunately, there are few other examples of the term’s use during this period.

The bell-towers of this Roman Catholic Church at Acoma Pueblo, New Mexico, combine features of Christian and Native American architecture.

Although the word “syncretism” was not in common use among the ancient Greeks and Romans, the practice of syncretism seems to have been very common. It was central to both Greek and Roman political culture as well as Roman and Greek religions. In many respects, the commingling of religions was a direct result of Roman conquest, slavery, and forced migration. Franz Cumont (1956, 4), a historian of religion, speculated, “Who can tell what influence chambermaids from Antioch and Memphis gained over the minds of their mistresses?”

During the time of Alexander the Great (Alexander of Macedon 356–323 BCE), Hellenistic culture was itself a mixture, having blended Persian, Anatolian, Egyptian, and later Etruscan-Roman elements into an overall Hellenic framework. It is apparent that the syncretic gods of the Hellenistic period enjoyed wide favor among the Romans. Serpis, Isis, and Mithras were the most prominent among these deities. The

goddess Cybele—as she was worshipped in Rome—was also highly syncretic.

In addition, pagan elements were incorporated into first-century Christianity. But—as with all religious syncretisms—not everyone agrees on the specifics. There are numerous and acrimonious debates with respect to “who, what, when, where, and why.” While a majority of classicists and New Testament scholars agree that syncretism has occurred within Christianity and is likely to continue, specific examples often give rise to heated debates.

The Romans—who saw themselves as the heirs to Greek civilization—identified Greek deities with members of the Etruscan and Roman pantheons. Interestingly, they accepted the Greek and Etruscan gods but rarely copied Greek or Etruscan rituals. Vague attempts to establish equivalencies between Roman, Greek, and Etruscan deities were seldom contested. But putative correspondences vary; for example, Jupiter was seen as a better equivalent for Zeus than the huntress Diana was an equivalent for Artemis. Classicists argued that Ares was not a good match for Mars. The Anatolian goddess Cybele—who was imported to Rome from her cult center at Pessinus—was identified as Magna Mater and given a matronly image that had been developed earlier in Hellenistic Pergamum. The Egyptian god Amun was borrowed from a Hellenized “Zeus/Ammon” after Alexander the Great’s quest for Amun’s oracle at Siwa. The Greek god Dionysus was imported into Rome as Bacchus, and the Anatolian Sabazios was transformed into the Roman deity Sabazius. Given these precedents, the Romans would have recognized few barriers to the worship of Isis or Mithras. Likewise, when the Romans first encountered the Celts and Teutonic peoples, they commingled these northern gods with their own gods, creating, among others, “Apollo Sucellos” (Apollo the Good Smiter) and “Mars Thingsus” (Mars of the War Assembly). As Charles Stewart and Rosalind Shaw have emphasized, attempts to explain syncretism by reference to perceived equivalencies and/or correspondences are often flawed. Equivalencies, they asserted, must be recognized by actors—and even when such

No difference there is between a temple and a mosque, nor between the Hindu worship or the Muslim prayer: for men are the same all over, though they appear not the same. • **Guru Gobind Singh (1666–1708)**

equivalencies are recognized, they do not have to be accepted.

Such identifications and equivalencies may stem from a Hellenic practice of identifying deities of disparate mythological traditions with their own. When proto-Greeks—whose language would later become classical Greek—first arrived in the Peloponnese over two thousand years ago they encountered localized nymphs and divinities already associated with important geographical features such as mountains, groves, caves, and springs—each of these geographical features had its own locally venerated deities.

Syncretism from the Renaissance to the Present

The term “syncretism” fell into disuse from the time of Plutarch to the time of the Renaissance. It was reborn with Erasmus (1466?–1536) and his reading of Plutarch. Erasmus modified the term “syncretism” in his *Adagia* (Adages)—first published in 1517—with reference to the coherence of dissenters despite their myriad philosophical and theological differences. Syncretism, for Erasmus, represented agreement among peoples with seemingly different beliefs and ideals. In a letter to Melancthon dated 22 April 1519, Erasmus specifically referenced the Cretans (borrowing from Plutarch) as an example of the adage “Concord is a mighty rampart.” Nearly a century later, in 1615, David Pareus of Heidelberg urged Christians to adopt what he called “pious syncretism” in opposition to the Antichrist, but few seventeenth-century Protestants seriously considered compromises that might bring about the ultimate reconciliation of Protestantism and the Roman Catholic Church. In the seventeenth century, Calixtus (1586–1656) sought to reconcile the various Protestant denominations with each other. He was ridiculed by Calovius (Abraham Calov, 1612–1686) for being an advocate of “syncretism.”

Nonpejorative connotations of the term “syncretism” began again in the eighteenth century with the publication of Denis Diderot’s *Encyclopédie*, which contained entries on “Eclecticisme” and “Synchrétistes, Hénotiques, ou Conciliateurs.” Although Diderot

published two separate entries, he equated syncretism with eclecticism and portrayed syncretism as the concordance of eclectic sources.

Throughout the nineteenth century, overt syncretism in folk beliefs was seen as a strong indication of the cultural acceptance of an alien and/or earlier tradition. Nevertheless, it was also recognized that “foreign” cults may survive or infiltrate other religions without an official, authorized syncretism. By the end of the nineteenth century, identities were no longer predicated on the existence of continuous and immutable cultures, and the concept of syncretism came to the forefront largely because it blurred local distinctions—a characteristic that made it useful for rulers of multicultural populations. At the same time, the rejection of syncretism, that is, antisyncretism in the name of purity and/or orthodoxy, helped to generate and legitimize a strongly felt desire for cultural unity. Contemporary celebrations of Christmas, Easter, and Halloween offer many telling examples of syncretism in practice. This is not a new phenomenon. The ancient Romans adopted pagan Yule traditions that eventually made it into Christmas celebrations (Christmas trees, Yule logs, and the like), and Roman Catholics in Central and South America have integrated a large number of elements that are taken from indigenous Latin American and North American religious traditions. It is of interest that religious leaders who oppose syncretism almost always express their opposition in terms of personal piety.

A number of so-called new religious movements like Reverend Moon’s Unification Church or L. Ron Hubbard’s Church of Scientology have openly embraced syncretism, while others—Christian fundamentalism and Islam are perhaps the most dramatic examples—have rejected syncretism as a devaluing of precious, genuine religious and cultural truths and distinctions. Examples of intense syncretism can be found in Romanticism and in various other “new religions” like mysticism, occultism, theosophy, paganism, and New Age. In the fine arts, the eclectic aspects in postmodernism are abundantly apparent.

Generally, the term “syncretism” has been positively regarded by social scientists. Yet Stewart and Shaw

report that there is growing uneasiness with the term among anthropologists who have been influenced by postmodernism. Other anthropologists have devoted their attentions to showing that syncretism is not inevitable. It is possible, they contend, for two groups to live in close proximity and largely ignore each another. For this reason, scholars find it both necessary and informative to examine syncretism with respect to relations of power. In *Syncretism and the Commerce of Symbols*, Goren Aijmer dramatically shifted the direction of research by asking, “Under what specific conditions do people in any one group pay attention to the cultural symbols of another group?” (1995, 27). Often, it seems that syncretism has been most intense whenever inequality between cultures has been the most pronounced. Equally important, war, conquest, colonialism, trade, migration, and intermarriage bring syncretism to the forefront. Race, gender, age, and social class are also factors. Scholars must examine the relationships between global and localized syncretisms. Are two or more religions influencing one another equally or is one dominating the rest? How does syncretism relate to issues of entrepreneurship and to theories of modernization?

In anthropology, the term “syncretism” is most closely associated with Melville J. Herskovits, who is best known for his research on the survival of African cultural traits among blacks in the Americas. Herskovits advocated an appreciation of what he called “syncretized Africanisms” and focused on various types of “acculturation” in order to address more general issues of culture contact. Again, there is need to recognize that acculturation (and syncretism) is not inevitable, and that all major world religions and cultures seem to be of composite origin.

Marked evidence of syncretism has been identified in New World religions such as Brazilian Candomblé, Haitian vodun, and Cuban Santería. These religions analogized various Yoruba and other African gods and selected Roman Catholic saints. Some Candomblé leaders have incorporated the spirits of American aboriginal leaders like Sitting Bull and Black Hawk into their rituals. The most syncretic New World

religion is perhaps Brazilian Umbanda, which combines African deities with a form of French spiritism attributed to Alan Kardec (1804–1869). In Brazil, French spiritism is also known as *Kardecism* or *Kardecismo*. Umbanda also incorporates local aboriginal spirits, African and Hindu deities, and North American aboriginal leaders.

Roger Bastide’s influential study *The African Religions of Brazil* attempted to account for syncretism by stressing historical processes like conquest and migration. He traced the various ways in which African, European, and aboriginal religions have come together in what he termed an “interpenetration” of civilizations. Rather than offering a psychological explanation, Bastide’s sociological approach focused on groups of people who were differentiated by sex, social class, and age. By contrast, Stephen D. Glazier’s research on the Spiritual Baptists in Trinidad focused on individual Baptist leaders and their practice of borrowing rituals from a variety of religious traditions but keeping these borrowed rituals separate in time and space. According to Glazier, one outcome of this process is a religion that is marked not so much by syncretism as by juxtaposition.

In South Africa, studies of syncretism have focused on independent churches. The earliest studies of African Independent Churches (AICs) were conducted by Christian missionaries, and the term syncretism was used in derogatory ways. Contemporary anthropologists—most notably J. Y. D. Peel—argued effectively that syncretism was not central to independent churches in South Africa because these churches represented reinterpretations of Christianity but never encouraged a mixture of Christianity and tribal elements.

It should be emphasized that authenticity and originality are not always dependent on the alleged purity and uniqueness of religions and vice versa, and that many so-called “original” religions—like the religions of Australian aborigines—are actually the result of a unique syncretism that has not occurred elsewhere. It is difficult to separate religion from the rest of culture. Scholars studying syncretism cannot specify their field of study in advance and must be sensitive to the ways in which people negotiate and redefine the boundaries

of their ideas and practices. For example, since Vatican II the Roman Catholic Church has implemented a concerted program of “inculturation” whereby local communities were encouraged to apprehend the Christian message “on their own terms.” Is this, too, a type of syncretism? Shaw and Stewart pointed out that global religions—like Christianity, Hinduism, Buddhism, and Islam—have been able to effectively “standardize” their responses to syncretism. They suggested, for example, that antisyncretism within Islam can be seen as a standardized response to global capitalism, labor migration, and travel—not least of which is participation in the hajj. Shaw and Stewart also underscored the need to examine problems of agency, especially when agency is ascribed to religious traditions without reference to religious specialists. A difficulty is that when one ascribes agency to a religion, religions are portrayed as having their own dispositions like “free-flowing rivers.” Such is seldom the case.

At times, syncretism is largely intentional, while at other times it is largely unintentional. Whatever the case, there are always unexpected consequences. Syncretism sometimes proceeds from misinterpretations and radical misunderstandings; for example, Christian missionaries working among the Ewe in Ghana identified one Ewe deity, Mawu, as the Christian God and labeled all other Ewe deities as “devils.” An unintended consequence of this labeling was that the Ewe devoted a seemingly disproportionate amount of ritual time to honoring their “devils.”

It is imperative for scholars to chart the increasingly complex interconnections between syncretism, social change, and resistance. Stewart and Shaw concluded their study of syncretism by suggesting that the term be recast as the politics of religious synthesis. A major focus, they postulated, should be on antisyncretism and the antagonisms shown by agents who are largely concerned with the defense of religious boundaries.

Renaissance

As increasingly urban, educated, and secular populations became dissatisfied with medieval values—first (circa 1350) in the Italian republics and principalities and then later north of the Alps—they sought to recover the knowledge and wisdom of the ancient world. A new and remarkable self-confidence in human agency resulted, and it sparked an intellectual, cultural, and artistic revolution known as the Renaissance.

The Renaissance was a period defined less by a span of time than by the application of certain ideas to almost every aspect of life. About the mid-fourteenth century in Italy, people realized that the essential values of the Middle Ages no longer suited an environment that was increasingly urban, secular, mercantile, and educated. In particular, city-states, such as Florence and Venice, required a new perspective that validated the lives of the wealthy merchants who governed their communities.

The Italian city-states had been made wealthy as a consequence of the crusades and the recovery of long-distance commerce, with Italian merchants dominating the carrying trade between Europe and the crusader outposts in the Levant (eastern shore of the Mediterranean), ferrying men, equipment, food, and goods across the Mediterranean. The cities of Pisa, Genoa, Amalfi, and Venice dominated this trade, which attracted large numbers of Europeans to the Levant and the Byzantine Empire in the Near East and a few to the Far East. The most dramatic episode in this expansion of Italian trade and influence was the conquest of Constantinople (Istanbul, Turkey) in 1204 by the crusader army of Baldwin of Flanders in northern Europe, an episode that the

Venetians used to gain greater influence in the lucrative Eastern markets.

Other Italian cities benefited economically as well, again driven by the vast explosion of money available as a result of trade. Florence was not a seaport but produced the finest woolen cloth in Europe, a product greatly sought by luxury-loving northern Europeans. The huge profits from this trade permitted Florentine merchants to increase their wealth by lending surplus capital at interest, that is, to become bankers as well

This panel from Ghirlandaio's fresco includes portraits of Francesco Sassetti's family, friends, and business associates. Sassetti, the director of the Medici Bank, commissioned the frescoes and the altarpiece in the Gothic-style chapel.

as merchants. Their banks gave the Italians a virtual monopoly over the money markets of Europe from the twelfth to the beginning of the sixteenth century. A direct consequence of this monopoly was the introduction of stable gold coins that could be used as reliable tender, free from the wild fluctuations of most medieval European coinage. The Florentines introduced the florin in the 1250s; the Venetians introduced the ducat in 1282. These currencies proceeded to dominate the economies of Europe for the next 250 years.

This wealth precipitated social and political problems, however. Merchants did not fit easily into the medieval worldview in which the clergy cared for souls and the landed nobility provided security and government. Tensions arose between the newly wealthy urban merchants—who were educated laymen but not noble—and the traditional ruling elite of the nobility. Venice escaped these tensions because it was surrounded by water with no landed territory dominated by nobles to cause friction; but Florence during the thirteenth century entered a period of great turmoil. The nobles resented the wealth and influence of those whom they considered to be their social inferiors, while the mercantile elite grew increasingly resentful of their lack of political control. The city became a battleground between the old and new elites, a division made more vicious because it was characterized by contemporaries as an ideological struggle between those who supported the sovereignty of the Holy Roman Empire

in Italy (the Ghibellines) and those whose allegiance was to the pope (the Guelfs). The former were generally old noble, landed families; the latter were generally newly enriched families who benefited from recent social mobility and the new mercantile economy.

Fragmented Italy

Italy had not been a united nation since the collapse of the Roman Empire. North of the kingdom of Naples, Italy remained a mosaic of independent states, ruled by princes or oligarchies of powerful families who received their authority from the Holy Roman emperor or the pope. Because neither the emperor nor the pope enjoyed sufficient authority to suppress the other, Italy remained fragmented until the nineteenth century. However, for the development of the Renaissance, this fragmentation was beneficial because it encouraged competition for the best artists, architects, and writers, and it permitted a degree of economic, social, and political experimentation impossible elsewhere on the continent.

In Florence the Guelf party ultimately triumphed with papal support, and the city reaped the reward of becoming the banker for the pope and the church. The old feudal families were tamed, disenfranchised, and excluded from government through a mercantile coup d'état in 1293 that created the republican constitution that would govern Florence throughout the

Renaissance. The city became an oligarchy ruled collectively by all adult male citizens who belonged to the twenty-one recognized guilds. It had an elaborate mechanism to forestall tyranny, entrusted to a collective executive of nine men. Even after the Medici family managed to assume political hegemony (influence) in 1434 under Cosimo de' Medici (the Elder, d. 1464), the city remained a functioning republic until the sixteenth century, with the head of the family merely manipulating policy behind the scenes. The greatest of the Medicis, Lorenzo the Magnificent (d. 1492), led the city through its celebrated efflorescence of culture and political influence, although he remained throughout his life only a leading citizen and not a prince.

The social, economic, and political revolutions of the thirteenth century in Italy obviously created powerful new groups of citizens with different ambitions and values from the old medieval world characterized by priests, knights, and peasants. The lives of citizens were secular; they were often highly educated

and very cosmopolitan, having lived abroad in many places as merchants. Moreover, they were “new men,” without great names or natural authority to support them: they had made their own way in the world, and they searched for a value structure that could offer comfort to them as bankers who took money at interest, despite the injunctions against usury, who needed advice concerning the government of guilds and cities, who wanted advice on the conduct of families, and who needed a culture that reflected their particular circumstances and that spoke to their role in this world as engaged lay citizens.

Francesco Petrarca (Petrarch, 1304–1374) first articulated this search. Born into an exiled Florentine family, he was a poet, philosopher, cleric, and diplomat. In his Italian poetry he celebrated human love and the desire for fame while advocating good style in Latin to clarify and externalize individual experience. Finally, he was interested in himself and his fellow humans and their experience in this life. He made popular once more autobiography as a genre, and he stressed the validity of the exploration of one's self and one's world.

Petrarch found a model for his ideas and his style in the ancient world. Rome was, after all, an urban, mercantile, secular society, originally republican like Florence, and possessed of a great literature that explored the human condition. He solved the problem posed by pagan authors in a Christian society by stressing that they were good men as illustrated in their writings: ancient writers, such as the Roman Cicero (d. 43 BCE), could advise the contemporary world in matters of ethics, even though Christian belief was still required for salvation. The ancient world, then, could safely be adopted as a model for both secular life and art: it could be reborn (renaissance).

Wisdom of the Ancients

These revolutionary ideas changed the European perspective, spreading through Italian republics and principalities and then north of the Alps. Human experience was now celebrated, and this life was

Giotto, *The Mourning of St. Francis*. Part of the artist's fresco cycle on the life of Saint Francis. Bardi Chapel in Santa Croce, Florence.

identified as something worth cultivating and studying. The ancients set a standard for Europeans first to emulate and then to surpass. To accomplish this, people had to recover the knowledge and wisdom of the ancient world; hence, the tools of philology (the study of language and word morphology), textual editing, archaeology, and numismatics were developed. To know their fellow human beings, people revived portraiture in sculpture and painting through the use of visually accurate anatomy and physiognomy (the art of discovering character from outward appearance). To reproduce what the eye sees as a tool to share people's understanding of the external world, Brunelleschi invented linear perspective in Italy early in the fifteenth century, and Alberti codified it. Buildings conformed to the precepts of Vitruvius, the Roman architect, and the vocabulary of design and decoration was adopted from the ancients. Taken together, these ideas and practices constitute humanism, which

became the central cultural and intellectual expression of the Renaissance; a direct consequence was a new and remarkable self-confidence in human agency. "Man is the measure of all things" and "Man can do anything he wills" became accepted beliefs within the humanist community.

This intellectual, cultural, and artistic revolution paralleled the economic and social revolution that was occurring. The virtual Italian monopoly on the lucrative long-distance luxury trade to the East galvanized peoples north of the Alps to find the means to challenge Italian economic dominance. The end of the Hundred Years' War (1453) and the English Wars of the Roses (1485) stimulated northern commerce; the crusade of rulers Ferdinand and Isabella of Spain against the Moors of Granada created a united Spanish kingdom by 1492. Also, the fall of Constantinople to the Turks in 1453 made Mediterranean trade more difficult and less profitable, even

for Italians. Searching for a new route to the East, Christopher Columbus, an Italian sailing for Spain, encountered the Americas in 1492; the Portuguese began exploring the coast of Africa until Vasco da Gama succeeded in 1497 in establishing an ocean route between India and Europe.

These voyages and the commercial connections and newly discovered wealth they brought changed the shape of Europe forever. The center of power on the continent shifted away from the Mediterranean (literally once the center of the Earth, *media terra*) to the Atlantic seaboard. Spain, Portugal, France, England, and later the Netherlands became dynamic nations, expanding beyond Europe into the empires they were building around the world, extending long-distance trade to places in Africa, the Americas, and the Pacific never contemplated by the Italians.

Renewed Self-Confidence

The result was a renewed self-confidence among Europeans that included a reinforced belief in the power of human beings to comprehend nature. Practical experiments resulted from this belief: science presupposes the validity of human observation and the ability to interpret it. Newly discovered plants and animals from outside Europe could be depicted through exact illustrations made possible by the Renaissance tradition of naturalism in art; skills such as reliable cartography for navigation were facilitated by related concepts such as linear perspective. Altogether, Europe assumed an energetic, outward-looking attitude that drove the voyages of discovery and the expansion of trade—events that resulted in new knowledge through contact with other peoples as well as a reconsideration of the place of Europe in the world, as evidenced by texts such as the English statesman Thomas More's *Utopia* (1516) and the French essayist Michel de Montaigne's essay *Of Cannibals* (printed 1580). Finally, new ideas could spread quickly and reliably through printing, developed in Germany in the mid-fifteenth century.

The decline of the Renaissance followed the decline of the principles that animated it; just as the Renaissance reached different nations at different times, so its eclipse occurred later in the North than in Italy. Events such as the invasion of Italy by King Charles VIII of France (1494) and the ensuing six decades of warfare on the peninsula, together with the loss of control of the Eastern luxury trade and almost continuous war with the Ottoman Turks, sapped both the wealth and the confidence of Italians. Also, the Protestant Reformation (a movement during the sixteenth century to reform the Roman Catholic Church) caused a reaction within

Raphael, *The School of Athens* (detail, 1509). Raphael's famous fresco re-imagines a scene from classical Greece. In the full view, Plato (right) and Aristotle (left) engage in dialogue surrounded by figures representing areas of knowledge they believed true philosophers must master, such as astronomy and solid geometry. Stanza della Segnatura, Palazzi Pontifici, Vatican.

From a competitive field of Renaissance architects, Pope Julius chose Donato Bramante's design for St. Peter's Basilica in Rome, photographed in 2004 from the roof of Castel Sant'Angelo; the foundation stone was laid in 1506. Over the next forty years, Raphael and Michelangelo, among others, added to and embellished the original plans. Today St. Peter's and the Vatican Museum are among the world's finest repositories of Renaissance artistry.

the Roman Catholic Church that often manifested itself in hostility to new or unorthodox ideas. The establishment of the Roman Inquisition (1542), the Index of Prohibited Books (1559), and the suppression of free inquiry in schools and universities made dynamic new ideas more difficult to accept. In the North the French Wars of Religion (1562–1598), the wars between the Catholic Habsburg ruling house and Protestant princes in Germany and the Netherlands, and the struggle between Europe and the Turks led to a movement away from Renaissance ideals and the economic and social conditions that had given rise to them. Although humanism continued in the form of classical studies, courtly behavior, elite

education, and cultural movements in art, architecture, and literature, its energy had been depleted and transformed by the religious, social, and political experiments of the Protestant Reformation, the Counter Reformation (a reaffirmation of the doctrine and structure of the Roman Catholic Church, partly in reaction to the growth of Protestantism), and the artistic and architectural style of the baroque.

Revolution—China

Revolution is a twentieth-century phenomenon in China, although the empire had a long history of peasant rebellions and dynastic overthrow. Revolution in 1911 formally ended 2,100 years of dynastic rule; revolution in 1927 railed against political chaos and a government that remained dominated by foreign imperialist powers; revolution in 1949 put the Communists in charge and culminated in the Cultural Revolution against those taking the “capitalist road.”

For much of the second half of the twentieth century, the founding of the People’s Republic in 1949 was seen as the decisive revolution, or perhaps the completion of earlier incomplete or “failed” revolutions in 1911 and 1927. With the cooling-off of the Communist revolution in recent decades, that metanarrative is open to question, and these earlier revolutions acquire more prominence in the long process of transforming an ancient agrarian-bureaucratic empire into a modern nation-state and industrialized society.

Even the word *revolution* was new in China in the late nineteenth century. Along with many Western ideas about modernity, it came to China from Japan as a neologism formed by taking the ancient Confucian term for mandate (*ming*), as in the Mandate of Heaven (*tianming*) that sanctioned a leader’s rule, and putting the Chinese word for “remove” before it. Thus, *geming* literally means: “to remove the mandate” (political legitimacy). But by the early twentieth century Chinese radicals already understood it in the sense of the American or French revolutions—establishment of a new political order. Closely associated with ideas of progress and popular sovereignty, it was

manifestly new and foreign, in fact, a response to the military and political humiliations China had suffered at the hands of industrialized Western powers since the middle of the nineteenth century.

Republican Revolution, 1911

The first revolution came rather unexpectedly, although for more than a decade there had been revolutionary agitation and small-scale uprisings, especially in the south. Most of these were led by Sun Yat-sen (1866–1925) and drew support from overseas Chinese business communities and the new generation of young intellectuals studying what was known as Western learning. Sun’s call to overthrow the “alien” Qing dynasty (1644–1911/12; the imperial family during the Qing dynasty was ethnically Manchu, not Han Chinese) strongly appealed to the ethnic nationalism they had learned largely from the West.

When the revolution broke out, almost accidentally from a botched military coup in the city of Wuhan in eastern central China on the Yangzi (Chang) River, lack of effective leadership in Beijing—the emperor was only a child—combined with widespread frustration over the Qing court’s inability to strengthen and modernize China, and imperial authority rapidly collapsed throughout southern and central China. Sun Yat-sen became president of a short-lived provisional government, but the revolution was soon hijacked by China’s most powerful military man, Yuan Shikai (1859–1916), a different kind of modernizer. Yuan used his military muscle to squeeze out Sun Yat-sen and his party’s elected representatives in the new National Assembly.

The economic success of Communist China has rested to a significant extent on the physical labor of its people. Here, a work gang discusses the day's schedule.

The revolution thus ended in apparent failure, with no democracy, no progressive political program, and China torn apart by civil wars after Yuan Shikai's demise. Nevertheless, the rather premature revolution of 1911, and the emperor's abdication in 1912, had ended 2,100 years of imperial bureaucratic government, replacing the hereditary emperor with a (supposedly) elected president, the Mandate of Heaven with the doctrine of popular sovereignty, and the old type of Confucian scholar-official with "modern men," whether trained in Western-style universities or modern military academies.

Nationalist Revolution, 1927

It was these modern men—and, with the growth of coeducation in the new schools, some women too—who carried the revolution to its next stage. The revolution of the 1920s was nominally led by Sun Yat-sen and his revived National People's Party (Guomindang, usually translated as Nationalist Party), but it mobilized much broader and more radical social forces than had the revolution in 1911.

The radicalism grew from several sources. First, there was the disappointment with the results of 1911 as the country fell into political chaos and remained under the domination of the foreign imperialist powers. Second, there was more rapid growth of the

modern sector of the economy, with factories and new social classes—Chinese capitalists and a nascent industrial working class—appearing in the coastal cities. Finally, of most direct import, there was the cultural iconoclasm of the New Culture movement, which blamed traditional culture and social habits (Confucianism was a prime target) for China's backwardness. The new universities, notably those in Beijing, were at the center of this intellectual revolution, which emphasized "enlightenment" and a broader concept of revolution.

But two external events precipitated the politicization of this cultural radicalism. One was the deeply felt disappointment with the Western democracies' decision to let Japan keep control over China's Shandong Province, which the Japanese had taken from Germany during World War I. To Chinese nationalists, this was a gross violation of Woodrow Wilson's principle of self-determination. The Bolshevik revolution in Russia offered an alternative, anti-imperialist vision of national salvation to the pro-democratic capitalist path that had originally attracted Sun Yat-sen. When recruiters from Comintern, Lenin's association of national Communist parties, came to China in the early 1920s, they found eager converts to Marxism and social revolution. They also used financial, military, and political aid to persuade Sun Yat-sen to reorganize his Nationalist Party and

Martyrs are needed to create incidents. Incidents are needed to create revolutions. Revolutions are needed to create progress. • **Chester Himes (b. 1909)**

launch a renewed revolution against imperialism and warlordism. The newly formed Chinese Communist Party also followed Moscow's guidance by accepting a subordinate position in a revolutionary united front with the Nationalists.

Thus the ideology of the second revolution was much more anti-imperialist in its nationalism and, at least potentially, much more anticapitalist in its social and economic policy, although Sun attempted not to alienate his more conservative supporters in the Nationalist Party and the Comintern insisted that China was ripe only for a bourgeois-nationalist, not a socialist, revolution.

The events of 1927 confirmed the Comintern's thesis in an ironic way. After Sun Yat-sen's premature death from cancer in 1925, tensions grew between the radicals and moderates in the revolutionary movement. In 1926 Chiang Kai-shek (1887–1975), commander of the new Nationalist Party army based in Guangzhou (Canton), launched the Northern Expedition (1926–1927) against the warlord armies. After successfully liberating the Yangzi River valley, including the modern metropolis of Shanghai, he broke with his radical allies, massacred the Communists, and brought the Nationalist Party under his control and formed a new government with its capital in Nanjing.

This marked an abrupt turn away from the radical agenda of the 1920s. Chiang abandoned most of the revolutionary social and economic policies, including Sun Yat-sen's plans for redistribution of land, in favor of militarily imposed political unification and nation building. Chiang and the Nationalist government achieved some success with this course during the Nanjing decade (1927–1937), before a Japanese invasion brought the government and the nation new challenges.

Communist Revolution, 1949

The Chinese Communist Party had been urban based in the 1920s, organizing industrial workers along conventional Marxist lines. After its defeat in 1927, it moved into the countryside, where Mao Zedong (1893–1976) emerged as the most successful leader of

peasant-based revolution. After relocating from south central to northwestern China in the famous Long March of 1935–1936, a reorganized party under Mao's leadership was positioned to take advantage of the withdrawal of Nationalist government authority from northern China to organize the peasantry in broad areas there to resist the invading Japanese.

During the eight long years of war, while the Nationalists' power and morale waned, the Communists grew in military power and popular support in the countryside of northern China. Combining anti-Japanese nationalism with social and economic improvements for the peasant majority, the Chinese Communist Party, now free of Russian influence, was much more ready for renewed conflict with the Nationalist government after Japan's surrender in 1945. The party's experience during these years—the "Yan'an spirit" of self-reliance, political will power overcoming material difficulties, and faith in the rural masses' innate revolutionary consciousness—was instrumental in gaining popular support and overcoming Nationalist military superiority in the seizure of national power by 1949. It also left a legacy of populist activism and guerrilla war mentality that was not always well suited to solving problems of economic development on a national scale.

The victory of the Communists in 1949 was in part the result of the Nationalist government's collapse from rampant corruption, administrative inefficiency, poor military strategy, and unsolved economic problems such as runaway inflation. But it was also due to the Communists' success in tapping into the main currents of modern nationalist aspirations for a strong, prosperous, and united country as well as the older socioeconomic grievances of the peasantry. That mixture was a potent revolutionary formula that seemed to have potential application throughout much of the Third World.

Great Proletarian Revolution, 1966–1976

In the first two decades of the People's Republic, the Communist Party oscillated between following the

Soviet model of a centralized, bureaucratic planned economy and more populist, rural-based strategies for building a modern, industrialized economy and an egalitarian, socialist society. The Great Leap Forward of 1958, with its rural communes, backyard steel furnaces, and frantic mobilization of the masses, was the most dramatic experiment in the Yan'an-inspired unorthodox developmental strategy that Mao favored. A disastrous economic failure, it was followed in 1966 by the Great Proletarian Revolution (Cultural Revolution, 1966–1976). Mao, appalled by the loss of revolutionary fervor in the Soviet Union and its new society of entrenched bureaucratic privilege, thought to prevent the same from happening in China by mobilizing frustrated students, low- and mid-level party members, and some elements of the military in a “revolution within the revolution.” This would not only remove those high-ranking leaders who were “taking the capitalist road,” but also revitalize the entire revolution.

With the help of the politically ambitious commander of the People's Liberation Army, Lin Biao (1908–1971), Mao purged almost all the top party and government leaders, inspired vast numbers of fanatically loyal revolutionary youth (the various bands of Red Guards), and put the country in turmoil for two years. He drew back, however, from completely dismantling the party apparatus that held China together, and the last eight years of his life were characterized by a complicated and somewhat paralyzing covert struggle between the acolytes of the Cultural Revolution's radical socialism and more cautious, economically oriented party bureaucrats.

China after 1978

With Mao's death in 1976 everything changed, but not right away. After a brief interlude under Mao's chosen heir, Hua Guofeng (1936–2008), by 1978 Deng Xiaoping (1904–1997) emerged as Mao's real successor. Also a veteran revolutionary from the Long March and Yan'an era, Deng abandoned Mao's revolutionary rhetoric, above all the idea of class

struggle and continuing revolution, and proceeded to systematically dismantle all of Mao's social and economic policies. Technological expertise replaced mass mobilization as the key to rapid economic modernization, and this meant both educational reform (no more politics before knowledge) and opening the country to advanced scientific technology from the West. Furthermore, economic incentives replaced socialist ideology as the motivator for economic growth. The communes were broken up into family farms. Private enterprise, at first on a small scale, but then on a large scale, was revived, foreign capitalist investment encouraged, and China embarked on the kind of export-driven industrialization that Japan, Taiwan, and South Korea had pioneered so successfully. As market economics gradually eroded the position of state-owned economic enterprises and consumerism spread throughout society, China became an integral part of a globalized capitalist economy. By 1998, little remained of Mao's socialist economy—and nothing of his campaign—to eradicate the capitalist mentality.

Did all this mean that the revolution was over, or was it, in Deng Xiaoping's formulation, “socialism with Chinese characteristics”? The official ideology remained socialist, and Communism the ultimate goal. But for the present capitalism is being allowed to develop its full productive potential, and successful capitalists are being recruited into the Chinese Communist Party. But the party still retains its absolute monopoly on political power; Deng himself sanctioned the ruthless suppression of the most serious challenge during the student uprisings at Tiananmen Square in 1989. Whether that makes the government still a revolutionary regime or just another one-party dictatorship is a moot point. Certainly the radical and violent upheavals of China's revolutionary past seem to be history, for now anyway.

Chinese Revolution in Global Perspective

All great revolutions reverberate far beyond national borders, and the Chinese revolution was no exception.

For a time, mainly in the 1960s and 1970s, China appeared to have inherited the mantle of Marxist world revolutionary leadership from an increasingly ossified Soviet Union. This was especially evident in Third World peasant societies, where the Chinese Communists vigorously promoted their experience with peasant-based revolution as a way to break free from capitalist imperialism and achieve rapid modernization. Lin Biao's short essay "Long Live the Victory of People's War!" (1965), succinctly expressed this ambition.

But Maoism and the Chinese model have had little real impact on political evolution in the Third World. The Naxalites in Bengal failed in attempts to import Maoist-style revolution into India. The most successful practitioners of "people's war," the Vietnamese Communists, depended on the Soviet Union for most of their military hardware, and in any event harbored a deep historic distrust of Chinese. The Khmer Rouge in Cambodia came the closest to being followers, but their ruthlessness exceeded anything in the Chinese experience, and their failure was more absolute. In Africa, Marxist movements leaned towards the Soviet Union. To be sure, there were some echoes of Maoism in Peru's Shining Path in the 1980s, and more recently rural insurrectionists in Nepal have proclaimed themselves Maoists. But on a global scale, it now seems that the Chinese model was much more specific to China's particular historical experience than relevant to peasant societies elsewhere.

There is also the overriding reality that since 1949 the percentage of peasants in the world's total population has continued to drop, until it is now well under 50 percent. With the poor and downtrodden of the

twenty-first century more likely to live in urban shanty towns than on the land, how relevant is a rural-based revolutionary strategy? Similarly, the model of radical egalitarianism that appealed to young Western radicals in the sixties and seventies has been almost completely discredited by the revelations of Cultural Revolution atrocities and post-Mao China's cozy relations with the international capitalist order.

Has the revolution left any legacy? Perhaps just the Maoist insistence that oppression and exploitation inevitably arouses resistance. Chinese revolution in the twentieth century was one of the great examples of such resistance, and it may yet be the inspiration for more.

The term *Cuban Revolution* applies to two phases of Cuban history since the mid-1950s. The first regards the actual military campaign that began in December 1956 with the landing by Fidel Castro and close to one hundred men in Oriente Province, which triumphed in January 1959 with the victory of his rebel army. The second, based on political alliances and ideologies, started immediately after Fidel Castro's entry into Havana.

Despite its retroactive symbolic and political importance, the actual military struggle of the Cuban Revolution that brought Fidel Castro to power in the 1950s was quite limited. Following Fulgencio Batista's coup d'état of 10 March 1952, Fidel Castro emerged as one of the leaders of the opposition to the dictatorship; that status was confirmed with the attack he led on the Moncada Barracks on 26 July 1953, despite its disastrous results. The romantic failure of this attempt and his subsequent trial (during which he made his famous speech, "History Will Absolve Me") made the twenty-seven-year-old Castro a political star. Following his pardon and subsequent exile to Mexico, Castro organized a group of men (Movimiento 26 de Julio, named after the Moncada Barracks attack) to lead a guerrilla war on the island. The group (including his brother Raul and the Argentine Ernesto "Che" Guevara, whom Castro had met in Mexico) was practically destroyed by regime forces upon landing in Oriente Province. Thanks to a great deal of luck, some favorable media coverage, Castro's considerable charisma, and the ineptness of the dictatorship's army and police, the small band was able to survive 1957 in the Sierra Maestra range in Cuba.

Beginning in 1958, the rebel army began more ambitious, but still quite limited, military offensives culminating in the battle of Santa Clara of 17 December 1958. Partly due to the appeal of the rebels and the venality and atrocities of the regime, popular sentiment and even that of the American embassy had overwhelmingly gone against Batista by midyear. On New Year's Eve Batista resigned and the government fell into Castro's lap. From the beginning, the limited nature of the conflict produced debates on the relative contribution made by the rebels in the *sierra* (mountains) and more middle-class opponents in the *llano* (city). (Despite later attempts to emphasize its role, labor was either a fairly passive actor or actually on Batista's side.) Due to later ideological splits this historiographical debate came to be imbued with considerable fervor and importance. Despite these arguments, the important lesson to be taken from this first part of the Cuban revolution was that authoritarian regimes such as Batista's were not so much defeated as they collapsed from their own contradictions and inadequacies. A similar pattern would follow in Nicaragua and Iran in 1979.

The Second Revolution

The second stage of the Cuban Revolution began with the traditional dynamics of postrevolutionary politics: the breaking of alliances, divisions between moderates and radicals, postponement of elections, and the tightening of power by those with the best access to violence. While large parts of the opposition to Batista had been motivated by hatred of the dictatorship, many among Castro's group also sought to address the social inequities rampant in Cuba. While

Che Guevara remains a powerful revolutionary symbol around the world. Here, a banner with his photo is on sale in Athens, Greece, in 2003.

the island did possess a large (by Latin American standards) middle class and Havana appeared to be a first world city, the gulfs between white and black, rich and poor, and town and country were massive. The revolutionary regime faced the classic quandary of wishing to initiate dramatic social changes while respecting the constraints imposed by electoral democracy. Led by the Castro brothers, the regime chose to privilege the former.

By 1961, indications of a more socialist policy had produced the exile of large parts of the middle class and the active opposition of the United States. Having established his control over the armed forces, Castro was able to openly express his alliance with the USSR and defeat an invasion by U.S.-backed exiles at the Bay of Pigs in April 1961. The agreement between the United States and the USSR following the October 1962 missile crisis guaranteed the regime's longevity.

The next four decades saw the revolution proceed through a series of stages. In the first, political authority was further consolidated by Fidel Castro and the Cuban Communist Party. Until 1970, Cuba resisted the "Sovietization" of many aspects of the economy and the society, but following the disastrous "ten million ton" sugar harvest of that year, the regime's autonomy appears to have declined. Over the next

twenty years, Cuba behaved fairly much like the standard Soviet satellite with two critical exceptions: it had a much more acrimonious relationship with the United States, and it also followed an adventurous foreign policy, with Cuban military involvement in Angola and Ethiopia and considerable aid presence in many parts of Latin America and Africa. The policies of the regime remained fairly stable and the population enjoyed an increasing standard of living (at least as measured in education, health, and basic nutrition, if not consumer goods). Certainly by the mid-1980s, the revolution was widely admired as a social success (if a political and economic disappointment). The one major crisis involved the departure of over 100,000 Cubans from the port of Mariel in the spring of 1980.

Following the collapse of the Soviet Union in 1991, the island entered the euphemistically named "Special Period." This saw declines in production and consumption by nearly half and a real social crisis with hunger not uncommon by 1993–1994. The regime adopted a limited opening to global capital (but not capital from the United States), which produced a significant improvement in living conditions. Reliance on tourism and remittances (now the two biggest economic sectors), however, brought with it social difficulties. Cuba, for example, has not experienced a civil rights

movement or even an oppositional racial discourse. In many ways, racial relations on the island remain frozen in the 1950s, with a significant decline in the black–white gap in living standards but a clearly racist culture and a continued monopoly by whites in high government positions. This also means that whites predominate in the sought-after jobs in the tourist sector. Since the exile population is overwhelmingly white, remittances are also distributed in a racially nonsymmetrical way. This has created something of a “dollar apartheid” in Havana.

Outlook

Whether the revolution, as a political regime or as a social system, can survive the inevitable death of Fidel Castro is not clear. (On 18 February 2008, in failing health, Castro declined to seek reelection; on 24 February 2008 the National Assembly of People’s Power voted Raúl Castro as his successor; the assembly voted unanimously in response to Raúl’s request allowing Fidel to be consulted on defense, foreign policy, and the economy. As of early 2010, Fidel was still alive.) But the level of institutionalization of power is relatively low. Given the proximity of the

now-wealthy exile community and U.S. interests, it is likely that the revolution will not survive in its current state. Perhaps the most significant disappointment of the revolution is that it was unable to escape the historical tendency toward “sultanistic regimes” led by *caudillos* (military dictators). In at least this way, the Cuban Revolution did not represent a new stage of history, but merely a slightly different variant of an old theme in Latin America.

Fiscal crises and years of feudal repression were among factors leading to a revolution in France (1789–1799) marked by the storming of the Bastille, the guillotining of Louis XVI, and the Reign of Terror. Although the revolution abolished legal privilege based on birth and guaranteed freedom of religion, its legacy is ambiguous; gains must be seen in the context of the suffering produced by denunciations, purges, executions, and war.

The troubles that led to the French Revolution began with the Seven Years' War (1756–1763), a worldwide struggle in which France lost its colonial holdings in North America and India to Great Britain and suffered defeat on the European continent at the hands of Britain's powerful German ally, the kingdom of Prussia. The expenses of war had required King Louis XV (1710–1774) to levy new taxes on his population; and since the nobles were among the richest subjects in the kingdom, he refused to exempt them, despite their historical claims to such fiscal privileges. Paradoxically, this treatment contributed to the education of the king's subjects in egalitarianism. By treating them as equals, the king taught them to think of themselves as equals. Initially the nobility sought only to preserve its own privileges, yet when they saw that the monarchy was inflexible on matters of taxation, they demanded a say in government, thus echoing the Anglo-American principle of "no taxation without representation." In the process they whittled away at absolutism, or the king's right to rule without checks or balances, and prepared the realm for republican government.

Toward a Constitutional Monarchy

In addition to the political arguments raised by fiscal crisis of the Seven Years' War, defeat at the hands of the British provoked a desire for revenge, both at the royal court and in the metaphorical court of public opinion. The American Revolution of 1776 provided the awaited opportunity, and General Washington's victory at Yorktown (1781), which would have been impossible without French support on land and at sea, inflicted a wound on France's great rival. Yet this victory was as expensive as the defeat in the prior war had been, and though Jacques Necker, the finance minister of Louis XVI (1754–1793), had made it appear as though the state's coffers were well stocked, under his successor, Charles Alexandre de Calonne, it became clear that the kingdom was approaching bankruptcy. Calonne presided over the Assembly of Notables, a hand-picked body of nobles, clergymen, and a few wealthy commoners who were expected to approve his plan for a more participatory government in exchange for the privileged classes' greater shouldering of the tax burden. This plan, which involved elected assemblies for some provinces, was a tacit abdication of absolutism. Still, the Assembly of Notables did not consider itself qualified to approve the revolutionary measures, and instead demanded that the king convene a more venerable and representative body for this purpose: the Estates General. After widespread unrest during the summer of 1788, the king called a meeting of that esteemed group for May 1789 at the royal capital of Versailles.

The Estates General consisted of provincial delegates from the three traditional estates, or classes:

Jean-Pierre Louis Laurent Houel (1735–1813), *Prise de la Bastille* (n.d.). A defining moment of the French Revolution was the storming of the Bastille.

the First Estate (the clergy), the Second Estate (the nobility), and the Third Estate (the commoners). Yet it had not met since 1614, after which the increasingly powerful absolute monarchs had succeeded in suppressing this historical check on royal authority. Consequently it was unclear how the three estates would meet, deliberate, and vote. Most nobles favored the procedure of 1614, according to which the estates met separately and voted by order. Yet many members of the Third Estate perceived this as a form of disenfranchisement, since the privileged nobles and clergy would often vote together against the Third Estate. To remedy this injustice some commoners called for voting by head (together as one body) and a “doubling of the Third,” in other words, doubling its representation, measures which would have provided parity between the Third Estate and the other delegates. A more radical proposal came from the Abbé Sieyès, a priest who nevertheless sympathized with the Third Estate and who urged its members to break from the Estates General and declare themselves a national assembly. Sieyès argued that the Third Estate comprised over 99 percent of France’s population and was engaged in its most useful work. The privileged classes, by contrast, were small and parasitical. Therefore the Third Estate should make the laws by which the nation would be governed. Although most delegates were initially reluctant to

adopt such a radical stance, the intransigence of the nobility and the refusal of the king to break the deadlock made the Third Estate increasingly sympathetic to his position.

The Constituent Assembly and the First Constitution

On 17 June a group of deputies from the Third Estate followed Sieyès’s advice and declared themselves the National Assembly, the sole body authorized to make the nation’s laws. They invited members of the other estates to join them, but only as citizens representing the nation, not as delegates speaking on behalf of their castes. Strictly speaking, this was the truly *revolutionary* act of the French Revolution, since there was no legal precedent for acting in such a manner. (The subsequent storming of the Bastille prison fortress by Parisian crowds on 14 July 1789 showed the force of popular anger, which posed a threat both for the Third Estate deputies and the defenders of the old order, but it was not in itself a revolutionary act.) On 20 June the revolutionary assembly found the doors of its meeting hall locked and proceeded to the most convenient space available, an indoor tennis court. There the delegates took their famous oath not to disband until they had written a constitution for France. After some

The young are generally full of revolt, and are often pretty revolting about it.

• Francois la Rochefoucauld-Liancourt (1613–1680)

hesitation, the king accepted this act of defiance, but ordered the deputies of the other two estates to join the National Assembly, thus creating a more conservative body than would have emerged from the initial revolutionary assembly alone.

Indeed, the National Assembly, otherwise known as the Constituent Assembly, created a highly undemocratic constitution, which was completed in September 1791. By establishing stringent property qualifications for voting rights and still higher qualifications for eligibility for public office, the deputies ensured that ordinary people would have little say in the laws that governed them. Only one-sixth of men over the age of twenty-five were eligible to vote. Women, servants, itinerant workers, and slaves (until their emancipation in February 1794) were excluded from political participation. The contradiction between the discriminatory measures of the lawmakers and their egalitarian rhetoric—especially the Declaration of the Rights of Man and Citizen, passed in October 1789—fueled popular unrest. Consequently, alongside the juridical revolution of the legislature, a popular revolution raged in the streets of Paris and other cities, as well as in the countryside.

Despite the limits the Constituent Assembly attempted to place on the Revolution, and despite the prominent role of the king in what was essentially a constitutional monarchy, Louis XVI was averse to the Revolution. He was particularly offended by its nationalization of church property, an expedient designed to back a new paper currency, and its reorganization of the clergy into civil servants required to take an oath to the nation. He therefore plotted to escape with his family to the Austrian Netherlands (today Belgium), where royalist forces would protect him until such time as the Revolution could be suppressed. He was captured by the revolutionary national guard near the border and returned to Paris on 20 June 1791. His attempted flight further discredited the idea of constitutional monarchy and emboldened radicals determined to transform their country into a republic.

Warfare Abroad and the Convention at Home

The delicate monarchical system survived little more than a year after the king's abortive flight. The Constituent Assembly disbanded following the fulfillment of its oath to write a constitution for the nation, and in October 1791 a Legislative Assembly was elected. While this legislature considered questions of domestic importance, it became increasingly preoccupied with international matters. A party of radical "patriots" sought war against Austria and Prussia, countries that were harboring royalist émigrés and issuing hostile statements regarding revolutionary developments in France. The patriots found unlikely allies in conservative royalists within the court who encouraged the march to war for very different reasons. The latter expected an Austro-Prussian victory over the French army, many of whose officers had emigrated at the outset of the Revolution. Thus in April 1792 the king asked an eager Legislative Assembly to declare war on Austria, with other European belligerents joining the fray in the succeeding months.

War transformed the Revolution profoundly. Not only did the revolutionaries use the threat of foreign troops to whip citizens into a patriotic frenzy; the mobilization of troops created a volatile situation in which armed men might turn their weapons against real or perceived domestic threats. As volunteers from the provinces came to Paris to prepare for assignment to the front, they encountered the most radical elements of the urban revolution. They heard the speeches and read the newspapers of the *sans-culottes*, those "without breeches" (i.e., without the stylish pretensions of the rich), and before taking on Austrian troops they prepared to fight the aristocrats in their midst. Convinced that neither the king nor the assembly would bring liberty and equality, the most radical revolutionaries, now fortified with weapons, mounted an insurrection on 10 August 1792.

After a bloody battle between insurgents and the king's personal guard, the insurgents emerged victorious. The royal family found itself under arrest, and the Legislative Assembly, now fearful of the forces it had

summoned into motion, abolished the undemocratic Constitution of 1791 and called for the election of a new legislature known as the Convention. Although women were still excluded from the vote, and indeed would not obtain it in France until 1946, the elections of 1792 were the first application of the principle of “one man, one vote” in modern world history.

A Republic Is Born

Unfortunately, this dramatic movement in the direction of democracy did not solve the country’s political problems. During the month and a half between the fall of the monarchy and the first meeting of the Convention, France was governed loosely by the outgoing Legislative Assembly and a self-proclaimed municipal government known as the Commune. In the first week of September, in anticipation of an Austrian march on Paris and an impending massacre of revolutionaries by brigands lurking in the city’s prisons, self-appointed judges presided over the judicial murder of over a thousand prisoners, many of them priests whose only crime had been refusal to take the obligatory oath to the nation. When the feared invasion by foreign armies failed to materialize and Paris calmed down, the newly elected Convention, which declared France a republic early on 22 September, was nevertheless preoccupied with the troubling question of the king’s fate. After divisive debates during the fall and winter of 1792–1793, on 21 January 1793, Louis XVI went to the guillotine, a decapitating instrument widely hailed as humane because prior to the Revolution beheading had been a privilege reserved for the high-born; more painful executions had been the lot of the common folk.

For many observers in France and around the world, this act of regicide took the Revolution beyond the pale. For devout Catholics in the Vendée region in western France, the killing of the monarch, whom God had chosen to rule over the kingdom, was not merely unjust; it was sacrilege. Partly as a result of this outrage, the revolutionary government found itself involved in a protracted civil war in the Vendée, one that would kill at least on hundred thousand

people. Civil war elsewhere in France, particularly in the south, resulted from conflict between centralizing Jacobins, who wished to see Paris take the lead in governing the country, and decentralizing “federalists,” who sought greater autonomy for the provinces. Both sides supported the republic and opposed monarchy, but they fought each other as bitterly as revolutionaries fought royalists.

The Reign of Terror

War, both foreign and domestic, provided justification for the revolutionaries’ most repressive laws. On the strength of the belief that traitors were endemic, the Convention passed a series of laws depriving suspects in political cases of due process and leading to thousands of judicial murders known as the Reign of Terror. Yet this tyrannical development was not simply a top-down policy. It had its roots in popular fears and resentments. In September 1793, during one of a series of insurrections that characterized the Revolution, armed crowds demanded the punishment of “traitors,” who were believed to be profiting from the war and hoarding grain while the people went hungry. The Convention responded with the proclamation, “Terror is the order of the day.” Institutionally the Terror was centered in the Committee of Public Safety, a group of twelve men who technically reported to the Convention but who for ten months dominated it. Maximilien Robespierre (1758–1794), the most infamous member of this committee, went to the guillotine himself when his enemies, anticipating their own execution, denounced him before the Convention and succeeded in having him prosecuted for treason. Shortly after Robespierre’s death on 28 July 1794, the legal apparatus of the Terror was dismantled. At least fourteen thousand people had fallen victim to it during less than a year.

The following year the Convention passed a new constitution, known as the Constitution of the Year III. (The revolutionaries had established a new calendar beginning with the declaration of the Republic in September 1792.) This constitution abolished universal male suffrage and restored property qualifications

for political rights. It also dispersed power so widely between a five-man executive branch (the Directory) and a bicameral legislature, neither of which was responsible to the other, that deadlock was the inevitable result. The only way to effect significant political change under the Directory regime (1795–99) was to mount coups d'état. Thus civilians made alliances with generals, who were increasingly powerful as France reversed early losses in the war with European rivals and began to conquer significant portions of Italy, Germany, and the Low Countries. Napoleón Bonaparte, who overthrew the Directory in the coup d'état of 18 Brumaire Year VIII (9 November 1799) and ruled as First Consul (and later as emperor) of a new, autocratic regime, was only the last and most successful in a series of military men who participated in such anticonstitutional adventures.

A Continuing Legacy

The French Revolution left an ambiguous legacy. It permanently abolished legal privilege based on birth and guaranteed freedom of religion. (France was the first European country to recognize the civic equality of Jews and Gentiles.) Other gains were more tenuous. With the exception of the election of the Convention, revolutionary France failed to provide real democracy, as either property qualifications or the atmosphere of political terror prevented the voice of the people from being heard. Napoleón reversed the 1794 abolition of slavery in 1803, and permanent abolition passed only during the revolution of 1848. Democracy, moreover, was limited to men, though the principle of equality inherent in revolutionary thinking became a central feature of the female suffrage movement and French feminism more generally. And the advantages of the Revolution must be seen

in the context of the pain and suffering produced by denunciations, purges, executions, and war. Whether the gains of the Revolution might have come to pass less violently, in other words, whether the Revolution was necessary, has been and is still much debated. Whatever one's position, the Revolution undoubtedly cast a long shadow over the subsequent two centuries, not only in France but around the world. Subscribers to revolutionary doctrines as well as conservatives, whose ideology was born of a determination to prevent revolution, would not be who they are if it were not for the French Revolution.

Revolution—Haiti

The revolution in Haiti began in 1791 and ended in 1804 with the establishment of the Republic of Haiti. It is the only slave revolt in history that led to the founding of an independent nation. The Republic of Haiti was the second republic (after the United States) established in the Americas.

Haiti is a small island nation that occupies about one-third of the island of Hispaniola in the Caribbean Sea. It was claimed for Spain by Columbus in 1492 and became a Spanish colony. The indigenous Indian population was soon wiped out by disease and the hardships of slavery and was replaced by slaves imported from West Africa. In 1697 Hispaniola was divided into French and Spanish sectors, with the French colony called Saint Domingue. Saint Domingue quickly became France's richest colony, with a large slave force working on plantations to produce sugar, coffee, cocoa, indigo, tobacco, cotton, sisal, and other agricultural products, all of which flowed exclusively to France. At the time the revolution began, the colony's population comprised about 20,000 whites, 30,000 free people of color (including many of mixed African and French ancestry), 500,000 black slaves, and at least 10,000 Maroons (escaped slaves who lived in settlements in the mountains). Slaves outnumbered nonslaves by about ten to one.

The start of the revolution is conventionally dated to 21 August 1791, but the origins of the revolt go back further in time and are complex. First, people in the colony were already divided about their allegiance to France. For a number of years prior to 1791, many whites and free people of color had been

becoming more and more disenchanted with French rule and especially French control of the economy, with all goods flowing to and from France. However, there were also divisions in both groups over loyalty to France, with some remaining strong supporters of French rule. Second, the slave system in Haiti was especially harsh (slaves in other colonies feared being sent there), and there had been frequent slave revolts, while the number of slaves fleeing to Maroon settlements in the mountains was increasing each year. Third, the French Revolution of 1789 weakened French control and created a cry for freedom in Haiti. Finally, Haitian slaves had developed a rural culture of their own centered on their religion (vodun) and extended families. Although often depicted as witchcraft, vodun was and remains a religion with its own set of beliefs, practices, and religious specialists.

What history now sees as the revolution began following a vodun ceremony in which a vodun priest named Boukman and several other men were designated leaders of the revolt. The bloody and destructive revolt pitted black slaves against white plantation owners. Interventions by the French failed, and whites and mulattos fled to the north. Some calm prevailed in 1796 when the religious healer Toussaint Louverture (c.1743–1803) took control in the north and restored order and stimulated some economic activity. In 1801 Napoleon sent 34,000 troops to the island under the command of his brother-in-law, Charles Leclerc. This force failed to retake the colony, although Louverture was taken to France where he died the next year. The following three years were marked by unrest, rebellions, massacres, and general civil war. On 1 January 1804, a new leader,

My grandfather was a voodoo priest. A lot of my life dealt with spirituality. I can close my eyes and remember where I come from. • Wyclef Jean (b. 1972)

January Suchodolski (1797–1875), *Battle at San Domingo* (n.d.). The slave revolt in Saint Domingue, on the island of Hispaniola in the Caribbean Sea, eventually led to the creation of the Republic of Haiti in 1804.

Jean-Jacques Dessalines (c.1758–1806), declared the independent Republic of Haiti. In 1806 Dessalines was assassinated, leading to renewed north-south civil war, with Henry Christophe (1767–1820) rising to power. Christophe instituted authoritarian rule, and fighting continued on and off until Christophe's death by suicide in 1820.

The years of revolt, massacres, and civil war left Haiti in a dismal state. At least 150,000 people died during the revolution. The new nation had no money, and its plantations and plantation system were in ruins. Land was distributed to individual farmers, but many of the plots were too small to be economically viable. The republic was short-lived and was followed by a series of dictatorships: between 1843 and 1915 Haiti had twenty-two leadership changes. Most of the people remained extremely poor, although there was a small, rich elite that ruled from the north. Mulattos fled to the north and dominated trade, collecting taxes on both imports and exports.

Haiti's situation was not helped by the hostility of the major world powers—the United States, Britain, Spain, and France—all of whom still benefited from slavery and saw the successful revolt as a threat to their coercive labor systems. The United States

Illustration of Toussaint Louverture reading the work of Abbé Guillaume Raynal, the French historian who examined the effects of colonialism on indigenous populations.

was right in this regard, as many slave revolts in the United States were modeled on those in Haiti. Haiti also became the focus of debates about the wisdom of emancipation for slaves and the ability of former slaves to rule themselves. The political instability and weak economy also meant that Haiti remained agricultural (even into the twenty-first century), while Europe and other nations in the Americas industrialized.

In 1838 France granted Haiti recognition after Haiti agreed to pay France 150 million French francs, an outlay that further damaged Haiti's already weak economy. The United States offered recognition in 1862; it occupied the island from 1915 to 1934 following years of Haitian political instability. After series of weak governments in the following decades,

the nation came under the dictatorial rule of the Duvalier family from 1957 to 1986. Since then, it has remained poor and has continued to experience political instability, despite or because of (depending on one's point of view) the intervention of the United States. Yet despite its many serious problems, Haiti has developed a rich artistic and literary tradition that is recognized around the world. Haitian people continue to demonstrate their resilience to the world as they rebuild their country and their lives after a devastating earthquake in January 2010,

Revolution—Iran

The Iranian Revolution of 1979, also known as the Islamic Revolution, involved the overthrow and exile of the country's Pahlavi-dynasty monarch, Mohammad Reza Shah. Led by Ayatollah Ruhollah Khomeini, the revolution gave rise to the founding of the Islamic Republic of Iran, with Khomeini assuming the role of Supreme Leader, the most powerful religious and political figure in Iran.

The Iranian Revolution of 1979 was a defining moment in modern Iranian history. It was a precursor to bringing Islam and Shi'a clerics into the center of political authority, an unprecedented notion in the Middle East and the Islamic world of modern times. (Shi'a Muslims are the branch of Islam comprising sects that believe Ali and the prayer leaders as the only rightful successors of the Prophet Muhammad.) The Iranian Revolution had its origins in several preconditions that were intertwined with other issues: political oppression, modernization/Westernization of Iran, and foreign dependency, eventually leading to the collapse of Mohammad Reza Shah's political order and its replacement by an Islamic republic.

Political Oppression

Political oppression in Iran can be traced to Reza Shah, founder of the Pahlavi dynasty. His autocratic role, particularly after 1930, is readily identifiable as an undermining of the constitution, especially when one notes how the deputies of the Majles (Parliament) were handpicked and how the appointments of the ministers were based upon personal loyalty to the shah (sovereign), not to the general public. In

addition, events brought about changes to the political atmosphere of Iran during World War II. Germany invaded the Soviet Union, and Iran, having already declared neutrality, refused the Soviet and British request that the allied forces be allowed to transport lend-lease material through its territory to the Russians. This refusal by Iran turned the request into an ultimatum and eventually led to invasions and occupation by England and Russia. Reza Shah was forced into exile and replaced with his twenty-two-year-old son, Mohammad Reza Shah.

The young shah's lack of political experience inaugurated a period of political freedom that subsequently produced organized political parties with the authorization to publish their own newspapers, naturally giving birth to a new era of ideological rivalry between political contenders. This rivalry ultimately underwent a series of internal conflicts among the nationalists who dominated the Majles under the leadership of Dr. Mohammad Mosaddeq and the pro-shah faction. To consolidate the nationalists' position in the government, Dr. Mosaddeq in 1949 created the National Front, a coalition representing different groups and political parties. Its primary goal was to restrict foreign interests, particularly the British domination and exploitation of the Iranian oil industry, as well as to safeguard the 1906 constitution that restricted the power of the monarch. The National Front's popularity reached great heights when Dr. Mosaddeq gained the approval of the Majles to nationalize the Anglo-Iranian Oil Company in 1951 and soon thereafter became the prime minister of Iran. British officials called for a boycott of Iranian oil, and through worldwide diplomatic maneuvers, major oil companies agreed to boycott Iranian oil.

Jimmy Carter with King Hussein of Jordan, the Shah of Iran, and Shahbanou (empress) of Iran, on 31 December 1977, two years before the start of the Iranian Revolution of 1979.

This boycott nearly brought the Iranian economy to a standstill. The economic hardship of the early 1950s caused a severe strain on the implementation of all of Mosaddeq's promised domestic reforms and, in turn, precipitated a decline in his popularity.

Fearing the spread of nationalization of domestic industries throughout the Middle East, along with the spread of Communist ideology in Iran, particularly through the popularity of the Tudeh (the masses) Party, the U.S. CIA and British intelligence executed a military coup d'état against Dr. Mosaddeq's government in August of 1953. After the coup the shah was returned to Iran from his self-exile and resumed control over the nation. He also settled the oil dispute through a consortium of eight European and U.S. companies by agreeing to fifty-fifty profit sharing by the Anglo-Iranian Oil Company. With the throne restored and the support of the United States, the shah began to take extreme measures to ensure the longevity of his dynasty. The first step toward this goal was the creation of an internal security force, with the help of the U.S. CIA and FBI, known as "SAVAK" (Sazeman-e Amniyyat va Ettela'at-e Keshvar or Organization for State Intelligence and Security). Its aim, for all intents and purposes, was to crush and demoralize opposition of any political nature, manipulate the behavior of citizens, and control and redirect public opinion in the interest of the regime.

In 1958, in response to mounting pressure for democracy, the shah created a two-party system consisting of the Melliyn (Nationalist) and Mardom (People) parties, neither of which constituted a worthy opposition party. However, in 1975 the two-party system merged into a single-party system known as "Rastakhiz" (resurgence), with membership required for all government employees and other people who were eligible to vote. Elections to the Majles were held; however, candidates had to have approval of SAVAK. Therefore, true representation of the people, via parliament, never emerged under the shah's regime. Mass censorship of television broadcasting, newspaper circulation, books, and journals and imprisonment of intellectuals, students, and trade unionists boiled over into total political frustration, resulting in mass demonstrations, strikes, and armed resistance against the shah's regime by the late 1970s.

Modernization/Westernization

The oil settlement of 1953 gave the shah the revenue to continue his father's aspirations of modernization. Since the First Seven-Year Plan (1948–1955) did not achieve its expectation, the shah initiated a second Seven-Year Plan which began in 1955. However, due to corruption and mismanagement, the plan did not achieve its expected goals. To demonstrate his popularity among Iranians and decrease the pressure for

reforms from the administration of U.S. president John F. Kennedy, the shah announced his six-point program popularly known as the “White Revolution” (or the “Revolution of the Shah and the People”) in 1963. It encompassed land reform, the sale of government-owned factories to finance land reform, women’s suffrage, the nationalization of forests, a national literacy corps, and profit-sharing plans for recruits in industry.

The goals of land reform were twofold: to gain support from the peasants living in agricultural villages of Iran and to eliminate the big landlords as an influential class. Although some big landlords lost their prominence, many retained their large holdings and became modernized commercial farmers and eventually were incorporated into the shah’s political elite. Land reform also failed to give sufficient amounts of land and resources to the majority of peasants; thus, a massive migration to the cities began, but the cities were not equipped to cope with the massive influx.

The national literacy corps was another important component of the White Revolution. The shah realized that for Iran to become modernized, the people of Iran would have to become better educated. Thus, high school graduate conscripts were recruited to spend fifteen months, in lieu of their compulsory military service of two years, in rural villages or small towns teaching in primary or adult literacy schools. With the help of the literacy corps and the opening of more schools, technical colleges, and universities, the shah succeeded in increasing the national literacy rate from 14.9 percent in 1956 to 74.1 percent by 1976. This increase was a major accomplishment by any standards. Nonetheless, these reforms undermined the religious schools and were resented by the cleric class, who had until then held the monopoly on education through their parochial schools. In addition, a higher literacy rate meant that political awareness in the cities, rural areas, and small towns would not be uncommon.

The women’s suffrage component of the White Revolution changed the political status of Iranian woman forever. Clerics and conservative families who did not like the emancipation of Iranian women opposed

this suffrage. Consequently, uprisings occurred in the theological seminaries and among shopkeepers in major cities. Clashes between the government and the opposition resulted in imprisonment and exile of the opposition leaders, including a less-prominent clergyman, Ruhollah Khomeini (1902–1989), who would go on to play a major role and become the leader of the 1979 revolution.

Along with the aforementioned reforms, other social and economic reforms were undertaken to further modernize the country. Among the most notable reforms was improvement of the infrastructure of Iran, including the construction of better medical facilities, improvement in the accessibility to health care, reforms in family laws, and expansion of women’s rights. The modernization and secularization of Iran made the shah’s leadership powerful and secure; however, at the same time his autocratic rule disassociated him from an important segment of society. Although the economic and social reforms brought many improvements, they also alienated many groups, such as the Bazaaris (traditional merchants), who consisted of hundreds of thousands of major merchants, shopkeepers, and artisans who could not compete in a Western-style economy. Lack of a viable political platform also alienated many intellectuals and students.

Foreign Dependency

The British and Soviets had dominated Iranian politics until the early 1950s, but the United States began to alter the role of the two competing powers in Iran after the 1953 military coup. The Truman Doctrine aimed to impede the spread of Communism in Southeast Asia and the Middle East. Because Iran had an extensive border with the Soviet Union, successive U.S. administrations saw Iran as a candidate for being influenced by Communist ideology. The first sign of the U.S. administration’s curbing Soviet influence came in October 1955 when Iran signed and joined the Baghdad Pact along with Iraq, Turkey, Pakistan, and Great Britain. Creation of this pact would ensure Iran of the U.S. military and economic assistance that it badly needed. This pact, along with an earlier

Ayatollah Khomeini, leader of the 1979 revolution.

U.S.-Iran mutual defense agreement, set up Iran to receive great quantities of military equipment.

During 1972 the tide turned in favor of the shah. Great Britain had pulled out of the Persian Gulf due to worldwide military cutbacks, and this vacuum was soon filled when the administration of U.S. president Richard Nixon underwrote the shah as the policeman of the Persian Gulf. This underwriting gave Iran *carte blanche* to purchase up-to-date non-nuclear weapons from the United States. During the 1973 meeting of the Organization of Petroleum Exporting Countries (OPEC), when the shah pushed to increase oil prices, in light of the 1973 Arab-Israeli War and an ongoing oil embargo, the timing was right for him to strengthen his presence as a leader in the region. With increased OPEC oil prices, the Iranian oil revenue augmented from \$2.3 billion in 1972 to \$20.5 billion in 1977, dispersing any monetary obstacle that might have prevented the shah from strengthening his military forces.

With the increase in oil revenue, Iran's annual military budget increased from \$1.8 billion in 1973 to \$9.5 billion in 1977, and the size of the military increased to 410,000 troops. The purchase of arms from the United States alone totaled \$6 billion by 1977. In 1976 the two countries signed a bilateral agreement that anticipated that non-oil and non-military trade between the two countries would reach \$15 billion by 1981. By 1978 more than fifty thousand U.S. military advisors and civilians were residing in Iran with extraterritorial rights (a privilege of immunity from local law enforcement of the host country). Ironically, the shah had now reinstated the same extraterritoriality act that his father had so fervently abolished in 1928. In general, the Iranian people never forgave Mohammad Reza Shah for that reinstatement.

Other factors leading to the Iranian Revolution included inflation, widespread corruption, inequities in income distribution, and the failure of political reforms. Hence, by 1978 a rapidly growing and resounding discontent existed among a majority of Iranians. Strikes and demonstrations became daily occurrences throughout 1978 and as a result hundreds died in clashes with riot police forces. The shah's inability to curb the situation encouraged the opposition to become more vigorous in their demand to end the monarchy. With the hope that a new government may be able to solve the political problems, the shah appointed one prime minister after another. They were, however, either old acquaintances or army generals who were already despised or mistrusted by the opposition. His final attempt was to ask Dr. Shahpur Bakhtiar, an opposition figure that had gone to jail for his anti-shah activities, to form a new government. Even though, on 3 January 1979, the parliament gave its approval to the new government, it was too late for Bakhtiar to gain the trust of the people and to remedy the situation. As a result, the shah realized that his departure from the country might help ease the discord, so on January 13, 1979, he named a Regency Council to take his place while he was out of the country. His departure on 16 January 1979,

however, marked the end of the Pahlavi era and the monarchy in Iran.

Meanwhile, Ayatollah Ruhollah Khomeini who was unceremoniously forced out of Iraq, where he had been in exile since 1963, was given permission to go to Paris. Suddenly the world's major media personalities discovered a simple religious man who opposed the tyrannical leadership of his native country. Khomeini's message was broadcast to the world and specifically to Iranians via various media outlets. His message was very simple: abdication of the shah and reinstatement of the Iranian Constitution of 1906. In Paris, Ayatollah Khomeini set up an Islamic Revolutionary Council with the task of establishing a transitional government, and a few days after his arrival in Iran on 1 February 1979, he appointed Mehdi Bazargan, a devout Muslim and supporter of Dr. Mossadeq and an anti-shah activist, as the prime minister of a provisional government, even though Dr. Bakhtiar's government was still in power. Dr. Bakhtiar and his government became increasingly unpopular to the point that he was forced underground and eventually fled the country on 10 February 1979.

As with any other political revolution, in Iran a period of uncertainty and political chaos ensued. Almost overnight, and continuing throughout the month of February, hundreds of Islamic Revolutionary courts headed by clerics were set up throughout the country to deal with the former regime's loyalists. High-ranking military officers, former prime ministers, ministers, and any who opposed the new government were summarily tried and executed without having any legal representation. Along with the Islamic courts, the formation of a Revolutionary Guard Corps with recruits drawn primarily from the lower classes and those loyal to Ayatollah Khomeini and Islam, was set up to defend the revolution against any possible military coup or civilian opposition. In order to abolish any sign of the old regime, on 30 and 31 March 1979, Ayatollah Khomeini declared a national referendum to choose the future form of the Iranian government. The choice was either monarchy or an Islamic republic. With this limited

choice, after the people had just gotten rid of the monarchical system, they overwhelmingly approved the formation of an Islamic republic over a monarchy. Soon after, the Council of Experts, mostly composed of clergy, was set up by Ayatollah Khomeini to draft a new constitution. The most debatable aspect of forming the new constitution was the principle of Velayat-e Fqih (the rule of jurist consult). In Shiism, it is believed that in the absence of the twelfth Imam—who was the direct descendant of prophet Muhammad through his daughter, Fatima, and his son-in-law and cousin Ali, and went into occultation and will return as the Mahdi or Messiah—the most learned jurist, one who knows the divine law and the will of the Mahdi, should be the supreme head of the government. With the approval of the new constitution, Ayatollah Khomeini was declared as such a jurist and as head of the new government was given more power than any other previous leader in modern Iran.

By November 1979, it was Ayatollah Khomeini through his mouthpiece, the Islamic Revolutionary Council, who was running the country, not Prime Minister Bazargan and his cabinet. The final showdown between the two political rivals came to a head with the seizure of the American Embassy by so-called "Students Following the Line of the Imam [Khomeini]." Bazargan and his moderate supporters adamantly opposed and condemned this act and demanded an end to the seizure of the embassy and the release of American Embassy personnel. But Ayatollah Khomeini eventually supported the students and called it Iran's second revolution. Two days after the takeover of the American Embassy, Prime Minister Bazargan resigned and Ayatollah Khomeini and his high-ranking clerics began to consolidate their political, economic, and social power in Iran.

In an attempt to take advantage of instability following the revolution, in September 1980, neighboring Iraq went to war with Iran seeking to end the revolution before it could take firm hold. Despite some early gains, Iran managed to recapture most of its lost territory by mid 1982, but the war dragged

on at great cost to both sides until August 1988. In effect, the war served to shore up support for the new government and the Islamic Revolution more generally.

The legitimacy of the Iranian government and the role of the Supreme Leader and the Guardian Council have not really come under serious challenge until the disputed presidential election of June 2009. Marred by claims of fraud, the disputed election result triggered mass demonstrations against the conservative incumbent, Mahmoud Ahmadinejad, and in support of opposition reform candidate, Mir-Hossein Mousavi. The protests met with a violent response from authorities and resulted in an unconfirmed number of deaths. While the election result is likely to stand, thirty years after the revolution and the establishment of the Islamic republic, the

legitimacy of the government is seriously being called into question.

Revolution—Mexico

The Mexican Revolution (1910–1920) stemmed from several sources: the alienation of elites who saw their political authority dwindling, the bitterness of peasants and workers who faced economic setbacks and famines, the dictatorial nature of the regime that had promised democracy, and the rise of economic nationalism. Among its successes was the return of more than 25 percent of the nation's land to the peasantry and rural workers.

During the first years of the twentieth century a wave of political upheavals swept across much of the world. The principal centers of upheaval—Russia and Iran in 1905, China in 1898 and 1911, and Mexico in 1910—were all centers of ancient civilizations undergoing radical transformations from

long-standing systems of cooperative industrial and agricultural production to modern capitalism and foreign influences. In Mexico during the years immediately preceding the upheavals, foreign capitalists backed by most of the domestic elite had taken over the communications, transportation, military, mining, timber, and textile industries, while both groups had taken over formerly village-owned agricultural and ranching lands on a massive scale. At the same time the government had repressed popular resistance and greatly increased dictatorial powers at the expense of the popular classes.

The new elite amalgam promoted commercial production at the expense of the rural workers who had enjoyed wide land-use rights for hundreds of years. The amalgam reorganized the peasants and rural workers, moving them from less commercialized

village properties and commercial estates, small mines, and artisan-run patios into larger capitalized entities. Foreign-born supervisors (low level management such as foremen) monopolized local authority and enjoyed wage differentials over the workers at an average of twenty-to-one, while managers (those who head an entire plant, mine, or other operation) earned as much as two hundred times their workers' wages. Foreign skilled workers enjoyed preferential treatment in an apartheid setting of segregated housing, unequal salaries, and discriminatory work assignments.

The Mexican Revolution (1910–1920) stemmed from several sources: the alienation of the provincial and local elites who saw their political authority eroded, the dashed hopes of the peasants and workers who faced economic setbacks and even crushing famines instead of the promised well-being, the increasingly dictatorial nature of the regime instead of an expected development of democracy, and the rise of economic nationalism. The revolution began on 20

November 1910, when Francisco Madero, a man of wealth from the northern state of Coahuila, called for all Mexicans to rise up and overthrow the dictatorship. He promised political democracy, equality before the law, and agrarian reform.

Three main groups emerged in the struggle against the dictator Porfirio Díaz. The first group, reflected by Madero and later by Coahuila Governor Venustiano Carranza and the Sonoran oligarchs Alvaro Obregon and Plutarcho Elias Calles, comprised the regional and local elites, who banded together for federalism, local and states' rights, and a nationalism with a more balanced distribution of power between themselves, the national government, and the foreigners. The second group comprised the leaders of the rural working people: Emiliano Zapata, Francisco "Pancho" Villa, and myriad others. The rural masses, which made up 80 percent of the population, had seen their share of land ownership fall from 25 percent to 2 percent under privatization, and their leaders sought

Armed soldiers line the entrance to General Francisco “Pancho” Villa’s headquarters in Juarez, 1914. Library of Congress.

the return of the land to the communities. The third group included the heads of organized labor, many of them anarchists. During the revolution they created the 150,000-member Casa del Obrero Mundial (House of the World Worker) and committed 5,000 soldiers and more than 500 women field nurses, known as *acratas* (those opposed to all authority) to the struggle. They wanted workers self-management in the factories, land for the peasants, and a reduced role for foreign capitalists. The differences between these three groups and the defenders of the ancient regime led to a complex civil war.

Madero Assumes Power

By the spring of 1911 widespread revolts by rural workers and peasants in support of Madero seized local power and were growing larger. Diaz quickly resigned with an admonition that “Madero has unleashed a tiger—let us see if he can ride it.” Assuming power in late 1911, Madero went to war with rural revolutionaries led by Emiliano Zapata in the sugar plantations

of south-central Mexico. Madero refused to return the privatized lands or to restore local governments. Then, in February 1913, the army staged a *golpe de estado* (coup d’état) and killed Madero. This killing led to the nationwide civil war. The rebels made Madero a martyr and rallied the public. This uprising spread rapidly and took on special strength in the North, where the rebels could buy arms by selling confiscated cattle to U.S. dealers. Meanwhile, U.S. President Woodrow Wilson provisioned Mexican dictator General Victoriano Huerta with arms until September.

During 1913 and 1914 the Villistas, an armed movement centered on the states of Chihuahua and Durango, formed under the leadership of town elites, cowboys, miners, and lumberjacks in favor of agrarian reform and political freedom and against debt peonage (form of bondage in which the laborer is held in place through the employer’s control of his debt accounts which are not paid off) and segregation. Meanwhile, the state elites of Coahuila, Sonora, and Sinaloa who had supported Madero rallied behind Venustiano Carranza, the former governor of Coahuila. Carranza, like

Madero, favored political liberalism. During 1913 and early 1914 Villa's forces marched southward until they controlled most of the North. Then, in April 1914, U.S. armed forces occupied Veracruz with heavy civilian casualties. During the summer the military government collapsed, but in November the U.S. military decided to support Carranza, and a new civil war began. The middle- and working-class-led Zapatistas and Villistas faced the forces headed by Carranza and the northern elites.

In a monumental step Alvaro Obregon, the military commander of Carranza's forces, gained the support of the Casa del Obrero Mundial by promising that the Mexican Revolution would be the first step toward worldwide proletarian revolution. Disorganized and poorly armed, Carranza's forces fled to the state of Veracruz. There, on 23 November 1914,

U.S. general Frederick Funston supplied them with ammunition and arms. By the end of 1914 Obregon commanded more than twenty thousand troops calling themselves "Constitutionalists" because they planned to reinstate the liberal constitution of 1857. As Obregon's troops defeated the Villistas and Zapatistas, Obregon allowed the Casa del Obrero Mundial activists to organize the workers in each city that his forces captured.

The Tide Turns

In January 1915 the fight between the Constitutionalist and Villista armies at El Ebano turned the tide in favor of the Constitutionals. Using several thousand "red battalion" troopers from the Casa del Obrero Mundial, Obregon crushed the Villistas by using the modern artillery and machine guns provided by the United States. Meanwhile, Carranza announced an agrarian reform program designed to undercut support for the Villistas and Zapatistas. In the spring of 1915 the Villistas and Constitutionals fought the largest battles of the revolution at Celaya and Leon. The indirect fire of Obregon's artillery and machine guns inflicted decisive defeats on the Villistas. The Villista army dissolved into guerrilla bands, and many soldiers returned to their lives in the small towns and countryside of the North. Reduced to guerrilla warfare, Villa remained a political force, mandating agrarian reform laws, the confiscation of the great estates, and labor laws regulating the northern mining and timber industries.

During 1916 Carranza consolidated his power. He demobilized the Casa del Obrero Mundial and its 350,000 members and red battalions, which totaled more than 4,000 troops. Carrying red and black flags in public demonstrations the Casa del Obrero Mundial proclaimed the goal of workers' control of production, and during the spring of 1916 it paralyzed Mexico City with a general strike. During the summer, however, the army crushed the Casa del Obrero Mundial during a second strike. In the North Villa began executing U.S. citizens, and in March he raided Columbus, New Mexico, to lure President

Taking it as a whole, Mexico is a grand city, and, as Cortes truly said, its situation is marvellous. • **Edward Burnett Tylor (1832–1917)**

Wilson into an invasion and expose Carranza as a traitor. U.S. general John “Blackjack” Pershing failed to catch Villa, but Carranza and Obregon had a more sophisticated agenda.

In February 1917 delegates from every sector of society promulgated a new constitution that satisfied most aspirations. It stipulated national ownership of natural resources, frontiers, and coastlines; universal male suffrage; land reform and municipal autonomy for the rural working class; and social justice for industrial workers as fundamental objectives for the new government. The revolution defeated the caste system that still characterizes much of Latin America; returned more than 25 percent of the nation’s surface, including much of the best land, to the peasantry and rural workers; initiated schooling for the indigenous population; and created a system of civilian government in contrast to the military dictatorships in support of oligarchy (government by the few) that still plague much of the Western Hemisphere.

Revolution—Russia

The Russian Revolution of 1917 was an event of enormous significance in twentieth-century world history. It marked the end of the distinctive society of czarist Russia, the world's largest country at the time, and the beginning of the first large-scale effort to construct a modern socialist society.

To many oppressed people in the world the Russian Revolution of 1917 represented a beacon of hope, promising that capitalist exploitation and imperialist domination need not be permanent. To most Western capitalist societies, however, the revolution was a threat of epic proportions—challenging private property, existing social structures, parliamentary democracy, and established religion. Its triumph in Russia initiated a deep rift in the global community between Communist countries and the capitalist democracies of the West.

Collapse of Czarist Russia

The first phase of the Russian Revolution occurred in February 1917, when the last czar, Nicholas II, abdicated the throne, marking the end of the Romanov dynasty that had governed Russia for almost three centuries. What had brought czarist Russia to this revolutionary turning point? Factors surely included the ancient inequalities, conflicts, and divisions of Russian society—the great gulf between a small land-owning nobility and a vast peasant class; the dominance of Russians over the empire's many other peoples; the absolute authority of the czar over all other groups in society.

Perhaps more important were the reforms that Russia's nineteenth-century czars made as they

After his death in 1924, Lenin became the focus of a quasi-religious cult, as reflected in this famous Soviet propaganda poster announcing: "Lenin lived, Lenin lives, Lenin will live." Poster by V. S. Ivanov.

attempted to modernize their country and catch up with the industrializing West. They ended serfdom in 1861, but the lives of most peasants did not improve dramatically. They promoted rapid industrial growth but did not anticipate the political demands of a growing middle class or the rising wave of protests by exploited urban workers. Despite modest political reforms and elections to a national parliament

Russians lie dead and wounded in the street after being shot with a machine gun manned by Bolshevik forces on the roof of a building.

(the Duma), the czar's government was exceedingly reluctant to share political power with other groups in society. As a result, various groups of revolutionaries emerged—many of them committed to socialism. Their activities only worsened the growing tensions of Russian society. But the pressures of World War I—massive casualties and economic breakdown—prompted mass demonstrations in the capital, St. Petersburg. Women, workers, students, and soldiers took to the streets in February 1917. Even the czar's most loyal supporters deserted him. These circumstances caused Nicholas II to vacate the Russian throne.

Social Upheaval

When the Russian monarchy collapsed, power was assumed by a provisional government, a coalition of leading middle-class liberals from the Duma and representatives of several mainstream socialist parties, the Mensheviks and Socialist Revolutionaries.

Although this new Russian government dismantled much of the old czarist state and promised a democratic constitution, its failure to end the economic chaos, to distribute land to the peasants, and to remove Russia from World War I opened the gates to a massive social upheaval during the summer and early autumn of 1917. Soldiers deserted in growing numbers; peasants began to seize the estates of their landlords; urban workers created highly popular grass-roots organizations called “soviets” to manage local affairs and to challenge official state authorities; minority ethnic groups demanded autonomy or independence. Russia was coming unglued and the provisional government increasingly discredited.

Bolshevik Takeover

These circumstances created an opening for a small radical socialist party known as the “Bolsheviks,” led by the highly disciplined and ferociously revolutionary

Vladimir Ilyich Lenin (1870–1924). As the only major socialist party that had not affiliated with the provisional government, it alone was untainted by the failures of that government. Thus, the Bolsheviks grew rapidly in popularity and in numbers of party members, especially in the large cities and among workers and soldiers. Their program, drawn up by Lenin, was far closer to the mood of the masses than that of the provisional government. It called for immediate peace, confiscation of land-owners' estates, workers' control in the factories, self-determination for non-Russian nationalities, and "all power to the soviets," which meant the overthrow of the provisional government. Lenin insisted that the Bolsheviks seize formal state power from the increasingly unpopular provisional government. On the night of 24–25 October, Bolshevik-led armed forces took control of major centers in St. Petersburg, but they did so in the name of the All-Russian Congress of Soviets, which was then assembling in the city. Thus, the Bolsheviks presented their takeover as a defense of the revolution and as a way of bringing a government of the soviets to power. So unpopular had the provisional government become that people put up little initial resistance to what the Bolsheviks called the "October Revolution." During the next several months Bolshevik-led soviets in many other cities also seized power and joined the revolution, at some times peacefully and at other times violently.

Civil War

Few people thought that the radical Bolsheviks could maintain power. Within six months the Bolsheviks found themselves in a bitter civil war against a variety of enemies—supporters of the czarist regime, middle-class liberals who favored the provisional government, and even a number of socialists who were offended at the Bolsheviks' unilateral seizure of power. Three years of bitter fighting ensued before the Bolsheviks staggered to victory in 1921, their hold on Russia, soon to be renamed the "Soviet Union," finally secure. Their opponents were divided, and some of them—known generally as the "Whites"—wanted to restore lost properties to the landlords. The Bolsheviks'

identification with the popular soviets and their willingness to endorse peasant seizure of land gave them an edge in competing for mass support. Their ability to integrate a number of lower-class men into the newly formed Red Army and into new institutions of local government provided a measure of social mobility for many. Because a number of capitalist powers, including Britain, France, the United States, and Japan, briefly entered the conflict on the side of the Whites, the Communists could present themselves as patriotic defenders against foreign intervention. The Russian Revolution had brought to power a Communist party—the Bolsheviks—which now proceeded to construct the world's first socialist society.

Revolution—United States

The American Revolution (1775–1783) is significant in world history for several reasons: the opportunity to weaken Britain's position drew the French monarchy into the conflict, which contributed to a financial crisis and the ensuing French Revolution; the rebellion inspired later changes in British colonial policy (at least where white settlers predominated); and the principles embodied in the Declaration of Independence inspired revolutionaries and nationalists elsewhere in the world.

The American Revolution took place between 1775 and 1783 and pitted colonists of the thirteen British colonies along the Atlantic coast of North America against Great Britain. The revolution was triggered by increased British efforts to control the colonies from 1763 onward, efforts largely designed to expand revenues for the British treasury. New taxes and regulations on colonial economic activity infuriated many colonists, accustomed to their own semi-independent colonial legislatures and considerable commercial latitude. Patriotic societies formed, and leaders began to invoke Enlightenment ideas about liberty and about popular control over government. (The Enlightenment was a philosophic movement of the eighteenth century marked by a rejection of traditional social, religious, and political ideas and an emphasis on rationalism.) Specific issues, such as the indebtedness of many southern planters to British banks, played a role as well. The patriotic Continental Congress assembled and began discussing independence in 1774. Outright clashes between armed militia groups and British soldiers began in Massachusetts in 1775. George Washington was named commander in the summer of that year.

Perhaps one-third of the colonists actively supported the ensuing struggle for independence, whereas another large minority preferred loyalty to the Crown. (Many Loyalists—also called “Tories”—fled to Canada and were stripped of their property.) Partisans included Virginia planters and New England political radicals, who agreed on Britain as a common enemy but disagreed about social change. A number of farmers, in what was still a largely agricultural society, participated in the struggle, as did some African Americans; the first colonist killed in the struggle was, in fact, an African American sailor. The colonies declared independence in 1776.

Fighting occurred in both North and South, with British troops, bolstered by German mercenaries, often holding the upper hand. Britain was hampered by cautious tactics but also by frequent overconfidence against the amateur colonial forces. The colonists had numbers on their side—although the actual number of combatants was small, with rarely more than fifteen thousand in the colonists' ranks at any given time. Many militiamen were part-time and ill trained, and funding was also a problem. France, and to a lesser degree Spain and the Netherlands, provided funds and weapons and direct military support after 1776, and this support was crucial in the latter stages of the revolution.

By 1781 fighting concentrated in Virginia, where the British general Charles Cornwallis had to yield to a combined French-American force at Yorktown. Desultory fighting continued for two years before a peace was signed in Paris to recognize the new United States, with territory running from Florida (ceded by Britain to Spain) to Canada, from the Atlantic to the Mississippi River. Britain feared even greater losses to its empire if war were to continue.

Significance

The significance of the American Revolution in world history rests on several bases. It was part of the ongoing colonial struggle among European powers because the opportunity to weaken Britain's position drew the French monarchy into the conflict. The revolution ultimately inspired later changes in British colonial policy toward greater flexibility and decentralization where white settlers pre-dominated; Canada became the first beneficiary during the first half of the nineteenth century. French expenditures in the war contributed to financial crises at home and helped lead to the need to call the Estates General (assembly) to consider new taxes and then to the French Revolution of 1789.

The example of colonial independence, the strong principles embodied in the Declaration of Independence and other writings by U.S. leaders such as Thomas Jefferson, and the institutions ultimately established by the Constitution all inspired revolutionaries and nationalists elsewhere. (During a brief period of confusion, after 1783, the United States attempted a loose confederation; the later establishment of a federal system, with checks and balances among legislature, executive, and judiciary would have the real influence in the long run.) French revolutionaries invoked the revolution in 1789 but also in 1830 and 1848; in the last revolution, a U.S.-style presidency was sought, although the effort misfired. The U.S. example loomed

large in the Haitian and Latin American struggles for independence (1798 and post-1810, respectively) because it provided the first modern instance of decolonization. The South American liberator Simón Bolívar, particularly, cited U.S. precedent in his hopes for a greater Colombia, free from Spanish control.

The U.S. political philosopher Thomas Paine summed up this aspect of U.S. influence, although with some exaggeration, claiming that the revolution “contributed more to enlighten the world and diffuse a spirit of freedom and liberty among mankind, than any human event that ever preceded it.”

Comparative Analysis

The revolution also deserves comparative analysis. It was not a major social upheaval, although a new generation of leaders did wrest power from their elders. Despite revolutionary principles, and some ensuing emancipations in northern states, slavery was not systematically attacked. Radical urban leaders such as Sam Adams in Boston were mainly controlled in favor of greater unity against the British, and the social structure and relations between men and women were not significantly altered. The revolution was far less sweeping than its later French counterpart. It was also unusually politically successful, compared with later independence struggles elsewhere, without a long, disruptive aftermath as in many revolutions and the Latin

He that rebels against reason is a real rebel, but he that in defence of reason rebels against tyranny has a better title to Defender of the Faith, than George the Third. • **Thomas Paine (1737 1809)**

Both the British and the Americans destroyed Native American villages during the revolution. This drawing shows the burning of an Iroquois village in New York State.

American independence movements. Good leadership and considerable political experience in colonial legislatures may help explain this success. The quick resumption of close economic ties with Britain after the war encouraged the U.S. economy. “New nation” difficulties, so common during the nineteenth and twentieth centuries, were limited in the United States, although rifts between North and South, united during the revolution, would soon resurface.

Finally, the revolution was, of course, a founding event for the United States itself. American nationalism, only tentatively developed before the revolution, was given a considerable boost, and the new political institutions established by the Constitution worked through their formative period during the 1790s and early nineteenth century with impressive success. Opportunities for westward expansion, initially in the territories of the Midwest and deep South, followed from the revolutionary settlement as well. The United States did not

emerge from the revolution as a major world power; indeed, it largely stayed free of major foreign entanglements. But the nation did begin to set its own course.

Revolutions, Communist

The great Communist revolutions of the twentieth century, especially those of Russia and China, drew upon the eighteenth century “liberal” or “democratic” revolutions of America and France. But the Communist revolutions, executed by highly organized parties guided by Marxist ideology, were committed to an industrial future. They pursued economic as well as political equality, and they sought the abolition of private property.

During the twentieth century Communist parties came to power in a number of countries and in a number of ways. In Russia (1917) and China (1949), Communist parties seized power as part of vast revolutionary upheavals that swept away long-established societies and political systems. In sparsely populated Mongolia an independence movement against Chinese control turned for help to the Soviet Union in the early 1920s and subsequently established a Communist state closely allied to the Soviet Union. After World War II Communist regimes were established in several countries of central and Eastern Europe, largely imposed by Soviet military forces that had liberated these countries—eastern Germany, Poland, Czechoslovakia, Romania, Hungary, Bulgaria—from Nazi rule. The local Communist parties that the Soviets installed in power initially had some popular support deriving from their commitment to reform and social justice and from their role in resistance to the Nazis. But in Yugoslavia and Albania Communist parties genuinely independent of the Soviet Union also came to power with considerable popular support.

After Japan’s defeat in World War II, its Korean colony was partitioned, with the northern half coming

This Chinese Communist poster—“Women can hold up half the sky. Surely the face of nature can be transformed”—reflects the Communist commitment to engaging women in the task of building socialism and its promise of a modern industrial future.

Poster by Wang Dawei, 1975, Tianjin.

under Soviet and therefore Communist control. In Vietnam a much more locally based Communist and nationalist movement under the leadership of Ho Chi Minh battled Japanese, French, and later

Workers of the world unite; you have nothing to lose but your chains.

• **Karl Marx (1818–1883)**

U.S. invaders and established Communist control first throughout the northern half of the country and after 1974 throughout the whole country. The victory of the Vietnamese Communists spilled over into neighboring Laos and Cambodia, where Communist parties took power during the mid-1970s. In the Caribbean Fidel Castro led a revolutionary nationalist movement against a repressive and U.S.-backed regime in Cuba and after coming to power in 1959 moved rapidly toward Communism and an alliance with the Soviet Union. Finally, a shaky Communist regime took power in Afghanistan in 1979, propped up briefly only by massive Soviet military support. At its maximum extent during the 1970s, Communism encompassed about one-third of the world's population and created a deep division in the world community.

Communist and Democratic Revolutions

The great Communist revolutions of the twentieth century, especially those of Russia and China, drew upon the “liberal” or “democratic” revolutions of the eighteenth century, such as the American (1776) and particularly the French (1789). Communist revolutionaries, like their French counterparts, believed that violent upheavals could open the way to new and better worlds constructed by human hands, but they worried lest their revolutions end up in a military dictatorship like that of Napoleon after the French Revolution. Like the French Revolution, those of Russia and China also involved vast peasant upheavals in the countryside, an educated urban leadership, the overthrow of old ruling classes, the dispossession of landed aristocracies, the end of ancient monarchies, and hostility to established religion. The Communist revolutions in Russia and China, like the French, “devoured their own children.” All three turned on some of their most faithful followers: in the French Terror (Reign of Terror, a period of the revolution characterized by executions of presumed enemies of the state); in Communist leader Joseph Stalin's purges in the Soviet Union; and in Chinese

Communist leader Mao Zedong's Cultural Revolution (1966–1976).

But the Communist revolutions were distinctive as well. They were executed by highly organized parties guided by a Marxist ideology; they were committed to an industrial future; they pursued economic as well as political equality; and they sought the abolition of private property. In doing so they mobilized, celebrated, and claimed to act on behalf of society's lower classes—exploited urban workers and impoverished rural peasants. The propertied middle classes, who were the chief beneficiaries of the French Revolution, numbered among the many victims of the Russian and Chinese revolutions. Communist revolutions, unlike the French and American revolutions, also made special efforts on behalf of women, granting them legal and political equality, sponsoring family reform, and actively mobilizing women for the workforce. Whereas the French and American revolutions spurred political democracy—although gradually—all of the Communist revolutions generated highly repressive authoritarian governments that sought almost total control over their societies, exercised by Communist Party elites or by single leaders such as Stalin, Mao Zedong, or Castro.

Comparing the Russian and Chinese Revolutions

Despite a common Marxist ideology and a disciplined party determined to achieve power, the Russian and Chinese revolutions differed in many ways. In Russia the Communists (Bolsheviks) came to power less than a year after the Romanov czarist regime collapsed in 1917, whereas the Chinese Communist Party had to struggle for decades after the demise of imperial China (1911/12) before seizing power. Thus, Russia's civil war occurred *after* the Communists took control (1918–1921), whereas in China prolonged conflict between the Communist Party and the Guomindang (Chinese Nationalist Party), led by Chiang Kai-shek, took place *before* the Communists seized power. Furthermore, Russia's Communists based themselves in the cities and drew their most devoted followers from the urban working class, whereas China's revolution

occurred primarily in the country's vast rural hinterland, with peasants as a primary source of recruits. This difference reflected the much greater industrial development of the Russian economy. Russia's peasants did join the revolution in the summer of 1917, but they did so spontaneously and without the active rural involvement of the Communist Party that was so important in China.

World war nurtured both of these revolutions, although in different ways. In Russia the Communists gained credibility by opposing their country's participation in World War I, arguing that it was an imperialist conflict that socialists scorned. However, in China the Communists gained much popular support by vigorously leading their country's opposition to Japanese aggression in World War II. China was a victim of imperialist aggression rather than a participant in it, and the Communists cast themselves as defenders of the nation far more decisively than did their Russian counterparts. Furthermore, because theirs was the first Communist revolution, the Russians faced almost universal hostility from established capitalist states. Later revolutions in China, Vietnam, Cuba, and elsewhere had the support of an established Communist power—the Soviet Union—in their struggles. They were joining an already established Communist world.

Ricci, Matteo

(1552–1610)

JESUIT MISSIONARY

Matteo Ricci, a missionary respected for his expert knowledge of China and the West, was the first Jesuit to live in Beijing. His deep understanding and tolerance for Chinese beliefs aided his missionary work and allowed for a greater acceptance of Catholicism among his converts.

The Jesuit missionary Matteo Ricci (1552–1610) is a leading figure in the history of the West's interaction with China. Despite the fact that few religious converts were made during his twenty-seven years in China, Ricci did lay the foundation for the early Catholic presence in the Middle Kingdom (the literal translation of Zhongguo, the name for China dating to ancient times), and his scholastic abilities, including his incredible memory and mastery of Chinese language and philosophy, along with his knowledge of mathematics, cartography, and astronomy, impressed many members of the ruling class. Through his translations he introduced the basic tenets of the Christian faith to China, most notably in his work, *The True Meaning of the Lord of Heaven*, as well as the math and logic of Euclid. Matteo Ricci is remembered for his role in pioneering the early cultural relations between Europe and China.

Born in the Italian city of Macerata, Ricci received his early education at home. In 1561, he entered a local school run by a religious order called the Society of Jesus, commonly referred to as the Jesuits, and seven years later he left Macerata to study law in Rome. In 1571, however, Matteo abandoned his legal studies and joined the Jesuit Order. Under the tutelage of the famous scholar Clavius, he studied mathematics and astronomy in addition to his religious training, which he received at Jesuit colleges in Florence and Rome. In

1577 Matteo left Italy and, after a brief stay at the University of Coimbra in Portugal where he studied Portuguese, he arrived in the port of Goa in India. While in Goa he taught Latin and Greek at the local Jesuit college and continued to prepare for the priesthood. Ordained in July 1580, Father Ricci was dispatched two years later to Macao on the coast of southern

China where he immediately began an intensive program of studying both written and spoken Chinese.

In 1583, Matteo Ricci accompanied Father Michele Ruggieri on a mission to establish a Catholic presence inside China. They settled in Zhaoqing, the administrative capital of the southern provinces of Guangdong and Guangxi, careful not to draw unnecessary attention to themselves while they worked to secure friendship from the ruling class. Abandoning an early strategy of integrating into Chinese society by wearing the orange robes of Buddhist priests, Fathers Ruggieri and Ricci donned the traditional costume of the Confucian literati elite instead. Recognizing that it was this class of society whose toleration, if not assistance, they required, the Jesuit missionaries worked to gain their acceptance by portraying themselves as scholars, moralists, and philosophers, rather than as religious priests.

While in Zhaoqing, Ricci mastered not only the basics of the Chinese language but also the philosophy of the ruling class. Relying on his tremendous memory, he could recite passages from the Four Books of the Confucian codex as well as selections from the classics of ancient literature and history along with volumes of commentaries on Chinese philosophy. This was a remarkable achievement given that no substantial dictionaries or language guides existed at the time. In the summer of 1589, Ricci and Ruggieri were forced to leave Zhaoqing after being expelled by an official who was hostile to the presence of foreigners. The Jesuit fathers then moved north of Guangzhou (Canton) to the town of Shaozhou where they remained for the next six years.

In 1595, after a total of twelve years in the south, Ricci was able to secure permission to travel north into the heart of China. Although he could not gain entry to the capital of Beijing, he did establish himself in the city of Nanchang in central China. Here he continued to cultivate friendships with members of the literati, and in 1597 he was named the superior of the China mission. In the fall of 1598 he was finally allowed to accompany a prominent Chinese official on a trip to the imperial capital. Although his first visit to Beijing was brief, Ricci was convinced that

the city was the same as Khanbalic, the capital of Cathay (an anglicized version of “Catai,” an alternative name for China) that had been described by the adventurer Marco Polo three centuries earlier. Father Ricci’s belief that Polo’s Cathay and Ming-dynasty China were one and the same was confirmed a few years later by his fellow Jesuit, Father De Goes, who travelled to China overland from India noting the accuracy of Polo’s descriptions of the region.

After leaving Beijing, Ricci settled in the secondary capital of Nanjing on the Yangzi (Chang) River where he continued his study of Chinese language and philosophy. He also reworked an earlier version of a map of the world that he had drawn while in Zhaoqing, and this extremely detailed map greatly impressed the local Confucian scholars. After nearly two decades in China, Ricci was at last granted permission to travel to Beijing, and despite efforts by the powerful eunuch Ma Tang to stop his visit, he entered the Chinese capital in January of 1601. The Ming emperor, who was impressed by the Jesuit’s gifts, which included a painting that utilized the technique of perspective, something untried up to this time by Chinese artists; two clocks that struck on the hour; and a music instrument called a spinet, granted him permission to reside in Beijing permanently. Ricci spent the final nine years of his life in the Ming capital.

During his time in Beijing, equipped with a command of written Chinese after years of dedicated study, Ricci began to translate European texts for publication. In addition to publishing his revised map of the world, he also oversaw the publication of many of these texts, including a summary of the Christian faith in a work called *The True Meaning of the Lord of Heaven* (1603), the first six books of Euclid’s *Elements of Geometry* (1607), and *The Ten Paradoxes* (1608).

In the end it was not Ricci’s religious teachings but his scientific knowledge—as demonstrated by his mastery of astronomy and use of sundials, clocks, and prisms—that impressed the Chinese court. His deep understanding of Chinese culture, combined with his willingness to accommodate his appearance and religious views to the traditions of the Confucian literary elite, paved the way for later generations of

Jesuit missionaries in China. However, Matteo Ricci's contention that the Chinese practice of Confucian rites, or "ancestor worship," was not a religious practice but a social custom was overturned a century later by the Congregation of Rites in Rome in 1704, a decision that ended an earlier period of cultural accommodation and toleration.

Rights, Property

Concepts of owning property (whether tangible or intellectual) and the contracts drawn up to regulate its use have taken shape in diverse forms throughout history. Examining property and contract practices of three groups—hunter-gatherers of the foraging (Paleolithic) era, agrarian “landed” communities, and industrial capitalist societies—demonstrates how property rights are closely connected with important values and structural aspects of a society.

Much contemporary political and popular discourse posits “property” as modern capitalist private property whose owner has the right to use the property, to exclude others from it (or regulate their use of it), and to alienate it. Private property is frequently seen as natural, desirable, or inevitable because it allows us to express or follow our self-interest, to do as we please with what we own, or to enact the final stage of a linear developmental history of which contemporary private property is the culmination. The history of property and contracts, however, shows that property has taken many different forms and a contract is but one type of exchange.

In thinking about the diversity of property practices, some important questions need to be asked. Who can own property? Private property can be owned by an individual person, a partnership, a corporation (a “legal person” in the eyes of the law), a family, a group, a tribe, or the state. “Common property” is open for use by a specific set of people, such as all townspeople. Sometimes not all individuals are eligible to own property: historically women (or married women), children, prisoners, and noncitizens have been disqualified.

What can be owned as property, in what ways can it be used, and can it be alienated (i.e., transferred by gift or contract)? Personal property, tools, shelter, and family burial grounds have frequently been owned by individuals or families, and in many societies they could not be freely sold but had to remain within the family, guild, or citizenry. Land uses have frequently been regulated, and sale prohibited. Some societies permit property in human bodies (children, wives, slaves), and others in human intellectual products, like written texts, songs, or cartoon characters.

Property practices are usually closely connected with important values and structural aspects of a society. The rules governing, and distribution of, property affect and reflect economic growth and decay, wealth and poverty, and political power and social status, as well as individual opportunity and psychological resources. Not surprisingly, then, property rights have been claimed, exercised, and contested throughout history with serious disagreement and often violence.

To explore the diversity of property and contract practices, it may be helpful to look at examples of property among hunter-gatherers, agricultural peoples, and industrial capitalist societies.

Property among Hunter-Gatherers

The earliest human communities were hunter-gatherers who lived primarily by hunting and gathering what nature provided, and sometimes also cultivating land. They lived in many parts of the world and, indeed, inhabit a few areas still. Contrary to standard myths, hunter-gatherers did have notions of property. For instance, Native Americans had

Native American (Siksika) girl with horse and pony, Montana. Before white settlers came to the American West, villages or tribes understood what marked their territorial boundaries and those of neighboring tribes.

Photo by Walter McClintock (1870–1949).

understandings concerning personal (or individual), familial, and tribal property. A bow made by a male Huron was likely to be considered his, and the basket made by a female Iroquois to be considered hers. At the same time, material accumulation was relatively unimportant to a Native American, while traditions of gift giving were extremely important to building and maintaining the political structure of a tribe. For instance, the chief distributed food and other resources to the members of the group—in a potlatch, for instance—in order to assure their well-being and solidify his social and political dominance, and one chief hosted another chief, or allowed another tribe to hunt on his property, to solidify intertribe relations. Similarly, familial clans maintained usufruct rights to planting fields and hunting grounds, but they would not prohibit others from entering or even from obtaining nonagricultural foods.

In addition, every village or tribe understood what marked their territorial boundaries and those of neighboring tribes. These boundaries were fluid, as tribes frequently exchanged territorial rights. As William Cronon, a scholar of the American West, puts it, these territorial transactions were more diplomatic than economic: Native Americans did not treat land and possessions as commodities to be traded in a marketplace. So land transactions between Native Americans themselves—in comparison to transactions between Europeans—“had more to do with sharing possession than alienating it” (1983, 67).

Agriculturalists and Landed Property

Even from the earliest times some places seemed better suited for agriculture than hunting and gathering. Agriculture has a long history in the Fertile Crescent, China, India, and the Nile River valley, where property boundaries were established and, by sophisticated geometry, reinscribed after each flood season. Because one acre devoted to farming or domesticated livestock can feed ten to one hundred times more people than a hunter-gatherer acre, agriculture generated food surpluses and settled civilizations, frequently headed by kings, ruled by bureaucrats, and marked by laws, many concerning landed property. Because it constituted power, land frequently could not be freely bought or sold; because it needed to be cultivated, workers might be owned as slaves or tied to the land by unbreakable contract as serfs. Some critics, of whom Rousseau is perhaps the most famous, have argued that agricultural property leads to a rich and powerful upper class, a downtrodden (frequently owned) and unhealthy laboring class, more work for all, and periodic famines when a major crop fails.

Others saw in the fixed, landed property of agriculture the possibility and goal of community. During the later years of the Zhou dynasty (1045–256 BCE), after the age of Confucius, the famous philosopher Mencius (c. 371–c. 289 BCE) looked back nostalgically to the Golden Age of Sages when—he believed—peace, order, and equality abounded because the

Page about trespassing from *Webster's Encyclopedia of Useful Knowledge and World Atlas* (1889), a book of general practical knowledge, including how to improve penmanship, handle legal issues, and make macaroni and cheese.

state had been founded on principles of equal land distribution. Hoping for the return of a similar age, he advocated the restoration of the “well-field” system of equal land holding. Thus, according to Mencius’s ideal and as the Chinese character suggests, each well-field was to encompass one *li* square, consisting of nine hundred *mu*. The well-field would thus be divided into nine equal parts, each consisting of 100 *mu*. From this, the eight peripheral plots would be given to eight families while the central plot would be owned by the state. Thus, all of the eight families would have to work the central, state-owned plot as a form of tax to the state. While Mencius believed such a system fostered equality, it did inevitably require a two-class system of “gentlemen” (magistrates, officials, and so forth) and “countrymen” (farmers). Even though most scholars doubt the historical accuracy of Mencius’s well-field system, it became a very popular model for later land reformers.

Similar visions—with a plurality of classes or social divisions—occurred in India and in medieval Europe, where the manor was the primary economic unit. The lord was understood to be the owner of his manor, and thus the peasants who lived on his land had to pay him rent by working on his land; peasants who farmed for a long time had effective tenure (or “copyhold”) to farm the land without being evicted by the lord, although the peasant could neither sell the land he lived on nor exchange it with another peasant or freeman. Mirroring the manorial system, feudal lords and vassals practiced fealty, in which a small lord would pledge his military allegiance to a greater lord in return for the greater lord recognizing and protecting his estate. Thus mutual obligations and duties bound together great lords, vassals, and peasants.

Trade, Global Expansion, and Capitalism

In China, medieval Europe, and most if not all agricultural societies, merchants engaged in trade. In classical Greece, Aristotle (384–322 BCE) distinguished merchant property from that of others in his *Politics*. Heads of households, Aristotle stated, exchange goods (and money) in order to buy goods to satisfy the household’s needs. Merchants, on the other hand, exchange goods in order to make money on the exchange; so the goal of exchange for merchants is profits. Within the limits set by laws, traditions, and religion, merchants bought and sold goods as commodities. Around the fifteenth century, European traders, with the support of their rulers, explored and expanded their trade, buying and selling commodities globally. With the development of commercial societies in England and Holland in the seventeenth century, land itself was coming to be seen not as inalienable by nature or tradition but as something that could be bought and sold; when these European societies colonized others, they brought with them and imposed their own ideas of property. As Locke stated, “in the beginning all the world was America,” waiting for Europeans to claim common or uncultivated land as their own private property or buy land from Native Americans who thought they were sharing its use.

Property rights are not the rights of property; they are the rights of humans with regard to property. They are a particular kind of human right. • David Friedman (b. 1945)

European expansion since 1492 and the economic dominance of European countries like Great Britain and then the United States has meant that capitalist practices of private property and free contract have been imposed or adopted throughout much of the world. Sir William Blackstone, the leading British legal theorist, in the 1760s pronounced the absoluteness of private property as “that sole and despotic dominion which one man claims and exercises over the external things of the world, in total exclusion of the right of any other individual in the universe” (1979, 2), language that suggests individual control of the material world and freedom of action (and that ignores the state’s power to tax and to fund public goods). With the development of corporate capitalism in the twentieth century, much individual property is now held as shares of stock and other financial instruments, so control and action have devolved to corporate managers, and the individual shareholder has become an “almost completely inactive recipient” of income (Berle 1954, 30–31).

Many have criticized capitalist private property. Marx sought to abolish private property because it limited individuality and freedom, alienating individuals and subjecting them to impersonal economic laws, Proudhon because property as theft subverted justice. Other critics, like the American utopian writer Edward Bellamy in *Looking Backward*, thought that national ownership of property would produce a more efficient and equitable economy with more leisure time. Arguments about whether private property increases freedom, efficiency, equity, and justice can be expected to continue, and the twenty-first century will probably see some new debates about property linked to changes in global trade (as the “free trade” disputes expand to include, for instance, distorting subsidies for private agricultural property in the developed world), environmental problems (as property’s relation to ecological degradation is examined), and intellectual property in an information society.

Intellectual Property and Copyright

Copyright, an aspect of intellectual property, can serve as a good current example of ongoing contestations of

and changes in property. The three major intellectual property rights—patent, trademark, and copyright—each protect different types of intellectual property in the United States. A *patent* grants an inventor the exclusive right (i.e., monopoly) to produce and sell his invention for a given period of time—usually a standard seventeen years. A *trademark*, which must be renewed every ten years, is a name, design, word, or cluster of words that signifies a firm’s identity to consumers: think of McDonald’s big yellow *M*, the “golden arches.” Copyright is an author’s legal right to control the production and distribution of her work—published or unpublished—for a legally established period of time, which has recently been extended to the author’s life plus seventy years thereafter.

Copyright protects an author’s *expression*, not his ideas or theories. That is to say, for example, Albert Einstein could never copyright his general theory of relativity because it was an idea, but he did possess copyrights for the books and essays in which he *expressed* the ideas of relativity. Although most authors register their work with the U.S. Copyright Office, one’s mere creation of a work is enough to establish one’s copyright over it. In most cases the owner of a work’s copyright is the work’s author, and the “author” is the primary creator of the work. The author may by contract reassign or sell his copyright to another party.

Copyright law has come under criticism recently for many reasons. As with laws governing many types of property, the law is subject to interpretation about what constitutes infringement of copyright. Currently, the U.S. Copyright Office defines infringement as any action involving the reproduction, distribution, performance, or making public of a copyrighted work without the express permission of the copyright owner. But one may be exempt from infringement charges if the reproduction is done by a nonprofit library, archive, or educational institution and is considered to be *fair use*. The boundaries between fair use and copyright infringement can be unclear or contested, for the law does not draw a clear line between the two.

Copyright law originally was intended to protect authors from having others copy and sell their

Page describing property deeds from Webster's *Encyclopedia of Useful Knowledge and World Atlas* (1889).

work for profit. With the explosion of file sharing, "peer-to-peer" (P2P) networks, copyright law and its enforcement have changed significantly. Statutes such as the "No Electronic Theft" Act (1997) and the Digital Millennium Copyright Act of 1998 state that individuals who reproduce or distribute copyrighted

material—even if they have no intention of profiting from it or are unaware of any harm they may cause—are subject to civil and criminal prosecution. The ninth circuit court of appeals in the case of *A&M Records v. Napster* (2001) reasoned that the Audio Home Recording Act (1992)—which exempted

from prosecution individuals using digital or analog devices to make musical recordings for their personal use—did not apply to individuals who reproduced copyrighted works on computers, and hence peer-to-peer networks such as Napster. In particular, file sharing seems to be most commonly practiced by younger, cyber-savvy generations, and thus the Recording Industry Association of America (RIAA) has increasingly made peer-to-peer networks on college campuses the target of their lawsuits. In May of 2003, four college students settled a lawsuit in which they agreed to pay the RIAA sums varying from \$12,000 to \$17,000. While actions taken against file sharers have had some effect on file sharing, it remains to be seen how copyright law, the market, and file sharing will evolve in response to peer-to-peer networks.

The new statutes have effects beyond file sharing. Because creators have copyright in their works, whether registered or not, and because many ordinary works lack a known or easily available public record of who currently owns their copyright, many works of culture from about 1920 are in a kind of limbo. They may be important or valuable culturally or as works of art; they may be disintegrating, as their pulp paper rots or their celluloid decays. But when, as is frequently the case, their ownership is unknown, no one will be willing to reprint or republish them—or even to preserve them in digital form—because of the possibility that the copyright holder will come out of obscurity and sue for infringement, even if the holder had no intention of preserving or publishing the work.

The geographer Lewis Mumford's observation—that all great historic cultures thrived by traveling along the natural highway of a great river—is particularly resonant today, as the world's rivers bear the brunt of human manipulation. Pollution and habitat loss (two main side effects of hydraulic engineering), as well as climate change, pose unprecedented challenges to agriculture, manufacturing, urban water supplies, and wildlife conservation.

By common definition, a river refers to water flowing within the confines of a channel (as suggested by its Latin root, *ripa*, meaning “bank”). More precisely, a river forms the stem of a drainage system that transports water, soil, rocks, minerals, and nutrient-rich debris from higher to lower elevations. In a broader sense, rivers are part of the global water cycle: they collect precipitation (snow, sleet, hail, rain) and transport it back to lakes and oceans, where evaporation and cloud formation begin anew. Energized by gravity and sunlight, rivers sculpt the land around them, wearing down mountains, grinding rocks, and carving floodplains through the earth's crust. As carriers of water and nutrients, rivers also provide complex biological niches for fish, sponges, insects, birds, trees, and many other organisms.

Rivers can be compared by basin size, discharge rate, and channel length, although there are no universally recognized statistics for any of these dimensions. The Amazon forms the world's largest drainage basin at approximately 7 million square kilometers, followed distantly by the Congo (3.7 million square kilometers) and the Mississippi-Missouri (3.2 million square kilometers). As regards discharge rate,

the Amazon once again stands supreme at around 180,000 cubic meters per second, followed by the Congo (41,000 cubic meters per second), the Ganges-Brahmaputra (38,000 cubic meters per second), and the Yangzi (Chang) (35,000 cubic meters per second). At around 6,650 kilometers, the Nile is the world's longest river, followed closely by the Amazon (6,300 kilometers) and the Mississippi-Missouri (6,100 kilometers). Other rivers with large area-discharge-length combinations include the Ob'-Irtys, Paraná, Yenisey, Lena, Niger, Amur, Mackenzie, Volga, Zambezi, Indus, Tigris-Euphrates, Nelson, Huang He (Yellow River), Murray-Darling, and the Mekong. Two rivers—the Huang and Ganges-Brahmaputra—also stand out for their huge annual sediment load, which makes them especially prone to severe flooding. There is no agreed-upon minimum size, length, or volume for a river, but small rivers are usually called streams, brooks, creeks, or rivulets. Great or small, rivers that form part of a larger drainage system are known as tributaries, branches, or feeder streams.

Although rivers vary greatly in size, shape, and volume, most rivers share certain characteristics. A typical river has its headwaters in a mountainous or hilly region, where it is nurtured by glaciers, melting snow, lakes, springs, or rain. Near the headwaters, swift currents prevail and waterfalls are common, owing to the rapid drop in elevation or the narrowness of the valley through which the river flows. As a river leaves the high region, its velocity typically slackens and its channel begins to meander, bifurcate, or braid. Often its floodplain broadens as it picks up tributary waters. As the river reaches its mouth, it usually loses most of its gradient. It becomes sluggish, allowing some of its sediment load to settle to the bottom, clogging

Edwin Lord Weeks (1849–1903), *Water Carriers of The Ganges* (n.d.). Oil on canvas. The Ganges, long a sacred site for Hindu ritual, is threatened by sewage and fertilizer pollutants.

the channel. The river responds by fanning around the sediment deposits, classically forming the shape of a delta (the fourth letter in the Greek alphabet, Δ), before emptying in a lake, sea, or ocean.

Unique climatic and geographic conditions determine a river's annual discharge regime (its seasonal variations in water quantity), but as a rule rain-fed tropical rivers flow more steadily year-round than do snow-fed temperate rivers. A river is called perennial if it carries water all or almost all of the time, and intermittent or ephemeral if it does not. A water-carved channel in an arid region is often called an arroyo or dry gulch if it carries water only on rare occasions. For hydrologists, the term *flood* refers to a river's annual peak discharge period, whether it inundates the surrounding landscape or not. In common parlance, a flood is synonymous with the act of a river overflowing its banks. In 1887, a massive flood on the Huang caused the death of nearly a million Chinese people. In 1988, flooding on the Ganges-Brahmaputra temporarily displaced over 20 million in Bangladesh.

Human Manipulation of Rivers

Rivers contain only a minuscule portion of the total water on earth at any given time, but along with lakes, aquifers, and springs they are the principal sources of fresh water for humans as well as for many plants and animals. Rivers are therefore closely associated with the emergence of settled agriculture, irrigated

crops, and early urban life. The great civilizations of Mesopotamia (literally “the land between the rivers”) from Sumer to Babylonia emerged beginning around 4500 BCE along the Tigris and Euphrates floodplains of modern-day Iraq. Egypt, as the Greek historian Herodotus once famously noted, was “the gift of the Nile.” The Huang spawned early Chinese civilization, just as the Indus produced the first cultures of southwest Asia, and the river valleys of coastal Peru shaped urban life in the Andes. “All the great historic cultures,” the geographer Lewis Mumford noted with only slight exaggeration, “have thriven through the movement of men and institutions and inventions and goods along the natural highway of a great river” (McCully 1996, 9).

For most of human history, river manipulation was slight, consisting mostly of diverting or impounding a portion of a river's water for the purpose of irrigating crops. Even modest modifications of this type, however, can have severe environmental consequences. In arid regions, salinization is a common problem. Unless properly drained, irrigated fields slowly accumulate the minuscule amounts of dissolved salts naturally found in soil and water. Over time this salt buildup will eventually render the fields incapable of growing most crop species. Siltation is a common problem caused when farmers and pastoralists deforest or overgraze river valleys, inadvertently setting in motion excessive erosion downstream. As the silt settles to the channel bottom, it elevates the

Otto Johann Heinrich Heyden (1820–1897), *The River Nile with the Gizeh Pyramids* (n.d.). Oil on canvas.

river above the landscape, making it more prone to flooding.

Ancient Roman, Muslim, and Chinese engineers possessed a sophisticated understanding of the art of hydraulics, as the still-extant aqueducts, canals, and waterworks of Rome, Baghdad, Beijing, and other Eurasian cities amply demonstrate. But river engineering as a mathematical science first emerged in Europe between 1500 and 1800 CE. The crucial breakthrough came when Italian engineers calculated the formula for determining the amount of water flowing in a river at any given time by measuring width, depth, and flow rate. Thereafter, water experts knew how to “tame” a river—that is, manipulate its banks, bed, and velocity in order to contain floods, reclaim land, and promote navigation—with a greater degree of precision, and therefore a higher chance of success, than had previously been feasible.

Today’s methods for controlling rivers are remarkably similar to those employed in the past—chiefly the construction of dams and weirs, the reinforcement of banks, and the straightening (and often widening) of channels—but materials and techniques have improved greatly over the past two centuries. Modern dams are designed to store water, regulate minimum channel depth (usually in connection with a lock), generate electricity, or perform all three tasks. Reinforced banks help keep the water in a designated channel, thereby reducing the frequency of flooding and opening up former floodplain for agricultural, urban, industrial, and other human uses. Channel

straightening gives a river a steeper gradient and thus a faster discharge rate; by reducing the total length of a river, it also facilitates the transportation of goods between ports. Collectively, these engineering methods transform a mercurial and free-flowing stream (a “floodplain river”) into a predictable deliverer of energy, goods, and water (a “reservoir river”). Nowadays, the Nile and Yangzi produce kilowatts for industries and cities, just as the Mississippi and Rhine transport freight for companies and consumers, and the Colorado and Rio Grande deliver water for farmers and homeowners.

Environmental Consequences of Hydraulic Engineering

River engineering fosters bank-side economic growth by opening up arable land, reducing floods, promoting trade, and generating electricity, but it also has a disruptive impact on riverine environments. The problems can be divided into two interrelated types: those that compromise the purity of the water in the channel (water pollution) and those that reduce the amount of living space in its channel and floodplain (habitat loss). Both typically result in a reduction in a river’s biodiversity.

River Pollution

Water pollutants can be divided into three broad categories: nutrient-based, chemical, and thermal. The

most common nutrient-based pollutants are fecal matter from untreated human sewage and agricultural runoff from phosphorus and nitrogen fertilizers. When introduced into a lake or river, these organic substances serve as food for phytoplankton (free-floating algae), which are huge consumers of the water's dissolved oxygen. If the river moves slowly, and if the "algal blooms" are large or frequent enough, the river will gradually become eutrophified (oxygen-depleted), with negative consequences for other organisms that require dissolved oxygen for respiration. The Po and Ganges are examples of sewage-fertilizer rivers.

The most pernicious chemical pollutants include heavy metals (zinc, copper, chromium, lead, cadmium, mercury, and arsenic), and chlorinated hydrocarbons such as polychlorinated biphenyls (PCBs) and dichlorodiphenyltrichloroethane (DDT). These

substances bioaccumulate; that is, they pass unmetabolized from simple organisms to more complex organisms, magnifying in concentration as they move up the food chain. The Mersey, Rhine, Hudson, Ohio, and Donets are all examples of industrial-chemical rivers.

Thermal pollution is a problem on rivers that have numerous nuclear-, coal-, or oil-generated power plants on their banks. The heated wastewater from the plant-cooling facilities artificially raises the water temperature, and the higher temperature in turn affects the type of species capable of living in the streambed. The Rhône and Rhine are examples of thermal rivers.

Most of the world's manipulated rivers can loosely be labeled "agricultural" since the majority of engineering projects are geared toward land reclamation

No man ever steps in the same river twice, for it's not the same river and he's not the same man. • **Heraclitus (544–483 BCE)**

(flood control) and the lion's share of dam water is still utilized for the purpose of irrigating crops. As industrialization spreads globally, however, chemical pollutants are increasingly becoming the single greatest threat to river systems; indeed, few rivers remain completely free of any trace of industrial contaminants. Today, the cleanliness or filth of a river is often more determined by the average income of the humans who live on its banks than by the number of farms and factories in its watershed. Wealthy nations have invested in urban and industrial sanitation plants over the past fifty years, and water quality has correspondingly improved. Poorer countries, unable to afford these techno-fixes, have seen their rivers continue to deteriorate.

Habitat Loss

Water pollution compromises a river's biological robustness by killing off organisms and by creating an unfavorable environment for nourishment and reproduction. But it is the engineering projects themselves that account for most of the habitat loss on rivers and are thus primarily responsible for the drop in biodiversity. Natural ("untamed") rivers contain an abundance of diverse biological niches: headwaters and tributaries, main and secondary channels, deep pools and islands, banks and bed, and marshes and backwaters. Channels provide longitudinal passageways along which organisms travel, while river edges provide access routes to the adjacent marshes and floodplains where many organisms find their nourishment and reproduction sites. Floodplains nurture trees, shrubs, and reeds, which help stabilize the channel bank while providing shade and protection to other organisms. A river basin hosts a complex web of life, ranging from simple organisms such as fungi, bacteria, algae, and protozoa, to more complex organisms such as flatworms, roundworms, and wheel animals, and on up to mollusks, sponges, insects, fish, birds, and mammals.

Engineering alters a basin's natural structure in ways that are detrimental to many species. Dams and weirs block a river's longitudinal passageways,

making it difficult for organisms to take full advantage of the channel's living space. Migratory fish are particularly hard hit because their life cycles require them to move from headwaters to delta and back again. Most famously, salmon disappeared from the Columbia, Rhine, and many other rivers when dams were built on their banks. Reinforced banks have a similar impact: they sever the links between a river's channel and its floodplain, depriving many organisms of their feeding and breeding sites. As a river loses all or part of its natural channel, bed, banks, islands, backwaters, marshes, and floodplain, it is transformed into a narrow and uniform rather than a broad and diverse biological site. Typically this results in a precipitous drop in both the number and type of species that it supports.

Aside from reducing the total amount of living space on a river, engineering can also trigger dramatic population upsurges in certain species, creating an ecological imbalance. The zebra mussel—a hearty algae eater and rapid reproducer—has migrated from its home in the Caspian Sea to the industrial rivers of America and Europe, displacing local mollusk species along the way. Similarly, after the completion of the Aswan Dam in the mid-1930s, snails infected with deadly schistosomes (parasitic worms) began to colonize the Nile's new irrigation canals, debilitating and killing Egyptian farmers and fishermen.

Responding to environmentalists and to reformers from within their own ranks (such as Gilbert F. White), engineers have developed new and more sophisticated methods of river manipulation over the past thirty years. More attention is now paid to preserving the original river corridor as channel beds and banks are fortified and dredged. Dams and weirs are fitted (or retrofitted) with fish ladders to ease fish migration. More floodplain is left intact. In some cases, rivers have even been re-meandered and rebraided so that they better replicate the natural conditions that once prevailed on their banks. Nevertheless, the recent Three Gorges Dam project on the Yangzi—the largest dam-building project of all time—serves as a reminder that the environmentally unfriendly practices of the past are still in widespread use today.

Most climate scientists predict that global warming will have far-reaching impacts on river systems worldwide. High mountains such as the Alps and Himalayas may begin to shed their snowpack earlier each spring. Higher evaporation rates may cause some regions to experience significant alterations in their annual precipitation patterns. Warmer water temperatures may make some rivers inhospitable to salmon and other cold-water fish. Rising sea levels may partially or wholly inundate the Netherlands, Bangladesh, and other delta regions. Although the effects on rivers will vary from region to region, collectively these changes will pose unprecedented challenges to agriculture, manufacturing, urban water supplies, and wildlife conservation.

Roads

The first roads were built to facilitate the movement of armies over uneven landscapes. Paved road systems reached new levels of sophistication during Roman times but fell into disrepair with the fall of the empire. The dawn of modern road building began with the invention of the automobile, evolving into today's intricate networks of street and highway systems.

Roads that allow marching men and wheeled vehicles to move easily across indefinite distances have existed for thousands of years. The earliest roads were built for military use, since rulers were eager to move armies as fast as possible to meet hostile forces wherever they might appear. But merchants and other travelers immediately benefitted from roads as well, and over time everyday use for peaceful purposes matched and eventually outweighed their military significance.

Road construction is not easy, for roads must often cross flowing water and/or dry streambeds and usually need specially constructed bridges to do so safely. On dry ground, rain erodes soft earth and forms puddles that quickly turn into impassable mud holes unless builders construct a pavement of flat stones, compacted gravel, concrete, or asphalt. Drains are often needed to keep the road surface intact for any length of time. In addition, since the invention of automobiles and trucks, curves and slopes must be designed to accommodate vehicles moving at high speed. This sometimes requires building tunnels, leveling hill crests, and moving millions of tons of rock.

Jan Asselyn (1610–1652), *Italian Landscape with the Ruins of a Roman Bridge and Aqueduct*. Oil on canvas. Many feats of Roman engineering—such as bridges and aqueducts—still exist as majestic ruins; with the fall of the empire Roman roads fell into disrepair.

Early Roads

Babylonian and Assyrian kings built the first road systems historians know of in modern Iraq. They did so for military purposes, beginning when horse-drawn chariots became supreme on battlefields after about 1400 BCE. The Persians later built a so-called royal road that ran all the way from their capital at Susa to the shores of the Aegean Sea, a distance of about 2,857 kilometers (1,775 miles). Xerxes's army used that road when invading Greece in 480 BCE, and the Greek historian Herodotus wrote that it took ninety-

three days to travel its length, an average of about 31 kilometers (19 miles) a day.

Other early empires in China and India also created lengthy road systems, but canal boats in China later became the main means of long distance transport, being cheaper and far more capacious than overland carriage. Roads assumed local, short-range significance in China thereafter, and when camel caravans became normal for long distance trade and raid (c. 200 CE), road building in the arid zones of central and western Asia lost its earlier importance. Wheeled vehicles became marginal wherever camels prevailed, so even the famous Silk Roads that connected China with western Asia after about 100 BCE were no more than a network of unimproved caravan tracks.

Roman Roads

Around the Mediterranean, however, the Roman Empire relied on a system of elaborately constructed roads designed primarily for military use but important for trade as well. Roads were a standard 8-meters (twenty-six-feet) wide, topped with multiple layers of

flat stones and gravel to produce a surface on which relays of horses could pull light, two-wheeled chariots as much as 120 kilometers (75 miles a day), while heavy carts were content to travel 24 kilometers (15 miles) a day. At its apex the Roman state maintained about 85,295 kilometers (53,000 miles) of such roads in Europe, western Asia, and North Africa, using them primarily to deliver supplies for army garrisons stationed along the frontiers.

In sub-Saharan Africa, Australia, and the Americas, where human portage was the prevailing form of transport, roads were not needed since human feet could traverse uneven ground just as well as camel hoofs. But, in Peru, Incan rulers constructed a road system rivaling that of the Roman Empire, presumably for military reasons. Two main roads ran from Ecuador southward for about 3,219 kilometers (2,000 miles), one along the coastal plain and a second inland through the high Andes. They were linked by side roads built along suitable river valleys. Incan roads were as much as 7.62 meters (25 feet wide); suspension bridges crossed wide ravines; and flat stone surfaces smoothed the way for human traffic and llama caravans.

Canaletto, *Grand Canal: The Rialto Bridge from the South* (1727). Oil on copper. Roads that need to cross flowing water require specially constructed bridges.

The road was new to me, as roads always are going back.

• Sarah Orne Jewett (1849–1909), *The Country of the Pointed Firs*

In Eurasia, the collapse of the Roman Empire (430 CE) disrupted road maintenance, and traffic soon decayed. The East Roman, or Byzantine, Empire—centered in Constantinople (later called Istanbul)—relied mainly on ships and navigable rivers for transport and gave up the effort to station troops on distant land frontiers, so eastern Europe, too, saw Roman roads deteriorate. Economic revival and population growth after about 900 increased trade, but for a long time no public authority existed that was capable of restoring a road system in any of the separate kingdoms and principalities into which Europe divided. Local cities did something to pave streets and public spaces, but overland hauling remained short range, slow, and expensive. Inland communities were almost self-sufficient for food and other essentials. Seafaring and boats moving along the slow-flowing rivers of the north European plain provided the principal means of transport.

Modern Systems

After 1650 or so the situation began to change when privately constructed, stone-surfaced toll roads, carrying swift passenger coaches and heavy freight wagons, proved profitable in a few unusually busy

locations. But Roman-style construction of multi-layered stone roads was expensive, so large-scale road building depended on the invention of cheaper methods of construction. After 1750, experiments began in both France and England using relatively thin layers of loose rock and gravel—as little as 224 millimeters (10 inches)—laid on top of ordinary soil raised above the level of adjacent ground and drained by ditches on either side. In England, John Loudon McAdam (1756–1836), appointed surveyor general of metropolitan roads in Great Britain in 1827, attached his name to this cheaper way of building roads, and a boom in “macadamized” road construction ensued. But the advent of railroads, beginning in the 1830s, soon eclipsed toll roads for most long-distance traffic.

Other European countries and European settlements overseas imitated the cheaper form of French and English road building very quickly but still saw railroads eclipse toll roads. Only when trucks and cars became numerous in the 1920s did a new era of road building emerge. Concrete slabs and/or smooth asphalt topping quickly replaced gravel roads, reducing dust and speeding driving. In the 1930s, Italy and Germany pioneered the construction of limited-access superhighways with a median

Henry Alken (1785-1851), *A Coach and Four on an Autumn Road* (n.d.). Oil on panel.

strip to separate opposite traffic flows. This set a new standard for speed and safety and in Germany was also designed for military use. The United States, after 1956, caught up by building an interstate system of limited-access highways that links all major cities in the country; wherever cars and trucks abound similar throughways have speeded traffic. But as vehicles multiplied they often increased traffic congestion. How long our present road system will retain its importance depends on the cost and availability of gasoline and diesel fuel or on the development of alternative technologies.

Roman Catholicism

Roman Catholicism traces its origins to Jesus Christ of Nazareth (born between 6 BCE and 6 CE and died between 28 CE and 30 CE) and regards the bishop of Rome (the pope, as the successor of Peter) as the visible head of the church. Roman Catholics worship Jesus as the Son of God and the Second Person of the Blessed Trinity. The religion had a profound effect on the development of Western civilization.

Found today in some 235 countries, the Roman Catholic Church is the largest of the Christian churches, with a world population of about 1.147 billion (as of 2007), or 17 percent of the world's population. The largest number of adherents is found in Brazil, Mexico, Philippines, the United States, and Italy. (In the United States Roman Catholics comprise 22 percent of the population and constitute the largest religious body.) This article is concerned only with the Roman (or Latin) branch and is divided into four sections: basic teachings, major historical developments, contemporary trends and problems, and Roman Catholicism in the non-European world.

Basic Teachings

The teachings of Roman Catholicism rest upon Scripture (revelation as found in the Old Testament and New Testament), tradition, and the magisterium, the teaching authority of the church. Tradition has enabled the church to adapt to new realities. It is closely linked to Scripture, and the interpretation of both is considered the prerogative of the magisterium. The expression of the revealed truth in Scripture may take diverse forms, such as history, prophecy, parable,

and allegory. A literal interpretation is not required. Throughout the Christian era, reformulation and adaptation have been characteristic of Roman Catholicism in moral teachings, liturgy, and societal roles. The process has involved change and continuity, conflict and consensus.

The distinctive marks of Roman Catholicism are unity, holiness, catholicity, and apostolicity. Unity means that each individual transcends all cultures and classes; holiness signifies that the church is intrinsically sacred despite the sins of its members, either individually or as a body; catholicity is the universality of the church; and apostolicity denotes faith, ministry, and the sacraments in communion with Rome. The Roman Catholic Church recognizes elements of itself in other Christian churches, and it does not require that a state be Catholic or that it enjoy any privileged status. It accepts the principle of religious freedom, and it holds that salvation is possible for all who act in good faith, according to their consciences.

There is a definite hierarchy in the Roman Catholic Church. As the successor of the apostle Peter, the supreme ruler is the pope. Elected by the College of Cardinals since the Middle Ages, the pope resides in Vatican City, a minute but sovereign state in the center of Rome. The other bishops are also seen as the direct successors of the apostles, and most reside in geographical and organizational units known as dioceses. The pope and the bishops are joined together in a collegial body, but collegiality does not lessen the papal primacy or affect papal infallibility in matters of faith and morals.

Just as the pope has primacy over the bishops, the bishops have the final authority in their respective dioceses. After ascertaining their orthodoxy, a bishop

In the eleventh century Pope Gregory VII brought about major changes in the church by eliminating the laity's role in choosing bishops.

ordains priests and deacons, who become his assistants. Priests must be male, and since the fourth century, enter upon a lifetime of celibacy. Deacons, also male, may be married. Most priests reside in ecclesiastical units called parishes. In addition to bishops, priests, and deacons there are monks and nuns who are members of religious orders and normally take vows of poverty, chastity, and obedience.

The "People of God" includes not only the clergy and the religious but the laity as well. Married or single, engaged in secular professions or occupations, lay persons are said to share in the mission of the church. As lay apostles, they assist bishops and priests in the conduct of church affairs, but they cannot act independently or in opposition to their religious superiors. Despite some softening by Vatican II (1962–1965) and more lay participation,

the church remains an authoritarian, hierarchical structure.

As defined by the Council of Trent (1545–1563), the vehicles of divine grace that enable a Catholic to attain salvation are the seven sacraments: baptism, penance, the Eucharist, confirmation, matrimony, Holy Orders, and anointing of the sick. Only those who have received Holy Orders are authorized to administer all seven sacraments. Other basic teachings of Roman Catholicism are the Trinity (the presence of three Persons in one God: the Father, the Son, and the Holy Spirit), the immortality of the soul, the resurrection of the dead, justification by faith and good works, an afterlife of reward or punishment, and special veneration of the Virgin Mary as the Mother of God. There is also veneration of the saints, but Catholics are directed not to pay an exaggerated attention to the saints.

The expression of Roman Catholicism takes the form of the liturgy, the rites and ceremonies of the church. The most important act of worship is the Mass, which is composed of the Liturgy of the Word (readings from Scripture) and the Liturgy of the Eucharist (Holy Communion). Like other aspects of Roman Catholicism, the liturgy, especially the Mass, has been adapted to regional environments, and the uniqueness of each culture is respected. Since Vatican II the vernacular has been used extensively, and although Gregorian chant is considered proper to the Roman liturgy, other forms of music are permitted.

Major Historical Developments

The beginning of the Roman Catholic community, as of other Christian bodies, is dated from the appearance of Jesus Christ to the apostle Peter after his crucifixion, burial, and resurrection. The apostles, like Jesus, were Jewish, as were the first Christians. What distinguished these early Christians from other Jews was their conviction that Jesus was the Messiah, that he had been resurrected from the dead. After the martyrdom of the Deacon Stephen, about 33 CE, these Christians, who had maintained close ties with the Temple, scattered and preached the Gospel wherever

they settled. With Paul (died c. 67 CE), Christianity came out of its Jewish mold, and Paul's missionary labors in the Mediterranean world made it the religion of the Gentiles.

Christianity spread rapidly in the Roman Empire. Women, especially widows and unmarried women, were active in the evangelization of pagan areas. Whether as preachers, deaconesses disbursing charity, or leaders of groups studying devotional literature, these women made their mark on the early church. Their influence, however, was short-lived; by the third century their activities had been curtailed, and they were gradually excluded from any clerical function. The patristic writings disparaged women. Saint Augustine of Hippo considered women innately inferior to men and saw them as symbols of carnality and original sin.

Another important development of Christian antiquity was the emergence of the concept of the primacy of Rome. Although Jesus had conferred preeminence on Peter among the apostles, he did not directly establish a papacy in Rome. Peter was almost certainly martyred in Rome, and thus Rome became a sacred place, a new Jerusalem for early Christians. The prestige of the bishopric of Rome because of its association with Peter was enhanced by the fact that Rome was the political and cultural center of the vast Roman Empire. In an age of heresies such as Arianism, Montanism, and Pelagianism, the bishop of Rome was frequently called upon to condemn unorthodox teachings and mediate jurisdictional disputes.

The first pope to claim primacy for Rome was Damascus (366–384 CE) at a council in 382 CE. Leo I (440–461 CE) made the formulation of the doctrine, which stated that the pope had the plenitude of power over the universal church. Papal authority was subsequently augmented by papal missionaries who evangelized new kingdoms. It was also strengthened by the secession of Eastern Orthodoxy, first in the ninth century and then in 1054 in a final and permanent break.

To the concept of the primacy of Rome was added that of the primacy of the pope over secular rulers as well. Thus in the eleventh century Pope Gregory VII

(1073–1085) and his successors ended the control of feudal lords and kings over the selection of bishops and abbots, but in the process, brought about major changes in Roman Catholicism. Secular and sacred domains were sharply delineated, and the role of the laity in the selection of bishops, which dated back to Christian antiquity, was completely eliminated. Absolute papal monarchy over the whole of Christendom reached its apogee under Innocent III (1198–1216) and Boniface VIII (1294–1303). In his quarrel with John of England, Innocent III claimed that temporal authority depended on spiritual authority. Boniface VIII went even further, maintaining in *Unam Sanctam* (1303) that every human being had to be subject to the pope in order to be saved.

Despite the extravagance of papal statements, Roman Catholicism contributed much to the development and achievements of Western civilization. The concepts of popular sovereignty and limited government were part of Catholic political thinking, and canon law, which was applicable whenever a sacrament or a cleric was involved, was the most humane and equitable law of the times. In education, first the monastic schools and then the cathedral schools and the universities made formal schooling more accessible than ever before, though men, and especially those destined for a clerical life, were the principal beneficiaries. However, until the High Middle Ages, talented women in female monastic establishments received a high level of education and made contributions to theology, philosophy, and literature.

Gothic art and architecture, the magnificent works of Dante and Chaucer, and liturgical art, music, and drama all owed their inspiration to Roman Catholicism. In the universities the scholasticism of Thomas Aquinas (1225–1275) provided a systemization of Catholic theology and philosophy that was to last well into the twentieth century. Members of religious orders, such as the Benedictines, Franciscans, and Dominicans, provided social services and medical assistance.

Marring these achievements were coercion in religious matters through the Inquisition, established by Boniface VIII, and the persecution of Jews. The

cruelty of the medieval Inquisition, which could employ torture to obtain confessions of guilt and could sentence those convicted of heresy to death by burning at the stake, varied considerably, depending on times and places. Wherever and whenever it existed it was a dreaded institution. As for anti-Semitism, ever since the beginning of the Christian era, Jews had encountered hostility when living among Christians, because they were considered guilty of deicide, of rejection of the Messiah.

As commerce and trade entered the medieval world, and as the proportion of Jews to Christians in these areas, especially money lending, increased, so did aggression against Jews. Jews were accused of avarice and economic exploitation, as well as of more serious charges, such as child murder and alliance with Satan. The worst of the persecutions took place during the Black Death of 1348/49, when Jews from Spain to Poland were accused of having deliberately caused the plague. In vain did the Avignon Pope, Clement VI (1342–1352), denounce this persecution, pointing out that the plague was striking Christian and Jewish communities indiscriminately and offering Jews a haven in Avignon.

The most traumatic event in the history of Roman Catholicism was the Protestant Reformation, which made the Roman Catholic Church a distinct and separate entity in the Christian world. By the beginning of modern times, the Renaissance, the scandal of the Great Western Schism ([1378–1417], when there were two or three who claimed to be Pope), the notorious immorality in the church from top to bottom, and the prevalence of superstitious practices produced skepticism among intellectuals, anticlericalism among the common people, and fodder for nationalistic rulers. The indulgence controversy following Luther's posting of the Ninety-Five Theses united all who had reason to oppose the papacy, and by the end of the century Lutheranism, Anglicanism, and Calvinism had cost the church the allegiance of half of Europe.

The Council of Trent (1545–1563) was convoked to deal with this crisis. Adopting a very rigid, defensive position, the Council defined the sacraments, especially those that had been questioned by the

Protestant reformers, and upheld traditional teachings regarding papal primacy, the hierarchical structure of the church, justification, the nature of the Mass, clerical celibacy, and both tradition and Scripture as the deposit of faith. Latin was retained as the mandatory language of the Roman Church. The legacy of Trent was a very conservative Roman Catholicism.

During the scientific revolution of the seventeenth century, members of the curia opposed the heliocentric theory proposed by Galileo and brought about his condemnation (to be reversed by Pope John Paul II in the 1980s). During the Enlightenment in the eighteenth century a climate of opinion that endorsed religious freedom, the power of reason, the possibility of a heavenly city on Earth, and a natural religion ran counter to the tenets of Catholicism. The era of the French Revolution and Napoleon (1789–1815) inaugurated a period when secular nationalism became the new religion. Almost all modern trends and movements were declared anathema by Pope Pius IX (1846–1878) in the *Syllabus of Errors* (1864). This pontiff convened the First Vatican Council (1869–1870), which formally defined the doctrine of papal infallibility in matters of faith and morals, much to the consternation of many Catholic theologians, ecclesiastics, and lay persons of the period.

Early in the twentieth century, Pope Pius X (1903–1914) railed against "Modernism," excommunicated "Modernists," and suppressed liberal Catholic theologians and historians. His successor, Benedict XV (1914–1922), ended the hunt for "Modernists." He also permitted Italian Catholics full participation in politics, something that had been forbidden by previous popes because Italy had been unified at the expense of the Papal States. During the era of totalitarianism, Roman Catholicism came under attack by Italian Fascism, Nazism, and Communism.

World War II broke out during the reign of Pope Pius XII (1939–1958), a controversial figure. As the war developed and Nazi atrocities, especially against Jews, became known, he was expected to speak out on behalf of Jews. For reasons that became the subject of heated debate after the war in both Catholic and non-Catholic circles, he alluded to the genocide of

A peaceful man does more good than a learned one. • **Pope John XXIII (1881–1963)**

Jews only in general, not specific, terms, even while providing Jews with money and refuge in the religious houses of Rome.

Contemporary Trends and Problems

With Pope John XXIII (1958–1963), Roman Catholicism embarked upon uncharted waters. A compassionate and approachable man, John XXIII's most momentous act was the convocation of a general council, known as Vatican II (1962–1965). In his inaugural address to the three thousand bishops and theologians drawn from all over the world, he declared that the "Church could and should adapt to the needs of the world." His message was one of *aggiornamento*. During the four sessions held between October 1962 and December 1965, every aspect of Roman Catholicism was explored, with a view to creating more openness and flexibility.

The Decree on the Church, instead of identifying the Roman Catholic Church with the Church of Christ, stated that the Church of Christ "subsisted" in the Roman Catholic Church. Papal infallibility was to some extent weakened by the introduction of the concept of collegiality—that is, the pope and bishops shared responsibility for the church. Even more revolutionary were the decrees on religious freedom, Jews, and relations with the other Christian churches. The Decree on Religious Liberty stated that every person "has a right to religious liberty." The Decree on Other Religions asserted that Christ's passion (the suffering culminating in the Crucifixion) could not be "blamed on all Jews then living, without distinction, nor upon the Jews of today." It deplored "the hatred, persecutions, and displays of anti-Semitism directed against Jews at any time and from any source." The Decree on Ecumenism called for dialogue with the Protestant churches to achieve agreement on theological differences. In this decree, the focus is not on a "return" to the Catholic Church, but on the spirit of Christ at work in the churches and communities beyond the visible borders of the Roman Catholic Church.

The air of optimism that pervaded Vatican II soon dissipated in the post-Vatican years. The dialogue

with Protestant churches made little progress with respect to such issues as papal primacy and infallibility, the nature of ordination, the relationship between Scripture and tradition, the nature of the Eucharist (a memorial service or transubstantiation) and the role of Mary in the Divine Plan. The "silence" of Pope Pius XII regarding the Holocaust was an irritant in many Jewish circles, despite the repeated apologies by Pope John Paul II (1978–2005) for the sins of the church against Jews.

Within the Roman Catholic Church there was increasing polarization, some Catholics believing that Vatican II had gone too far and others countering that it had not gone far enough. The positions of Pope John Paul II were generally conservative. Traditional morality in such matters as divorce, premarital sex, contraception, abortion, homosexuality, euthanasia, and genetic engineering was affirmed. The role of women in the church and clerical celibacy occasioned fierce controversy.

In the 1980s and 1990s, as traditional religious orders declined and the number of priests declined dramatically, women assumed liturgical and administrative positions in the church, serving as chaplains, seminary professors, and spiritual directors. Inevitably the question of the ordination of women came up. In an effort to end the discussion, John Paul II in *Ordinatio Sacerdotatis* unequivocally stated that the church did not have the authority to ordain women.

A revival of the issue of clerical celibacy was provoked by the priest sex scandal that rocked the Roman Catholic Church, especially its American branch. It became evident at the turn of the century that for decades bishops had moved priests who sexually abused children from one parish to another in an effort to avoid scandal. In 2002 the Vatican and the American hierarchy adopted stringent measures to purge the clerical ranks of offenders and to ensure the protection of children, but the extent of priest sexual abuse raised the question of clerical celibacy as the possible cause of such offenses. But the Vatican denied a link between celibacy and pedophilia and/or homosexuality, and reaffirmed the validity of a ban on marriage

for priests. The priest sex scandal, no longer confined mostly to the United States, resurfaced on Vatican soil some five years after the German-born Cardinal Joseph Ratzinger was elected as Pope Benedict XVI on 19 April 2005. Amid a papacy already beset with controversies that had offended Muslims, Jews, Anglicans, and many Roman Catholics, Benedict XVI and his direct subordinates were accused in early 2010 of neglecting to alert civilian authorities or discipline priests involved in sexual abuse when he was archbishop in Germany.

As the twenty-first century unfolded, discord and polarization seemed to foretell a new crisis for the church, paralleling that of the Reformation era. Yet most Catholics refused to abandon the church and sought instead a new identity, respectful of the past but adapted to the needs of society.

Roman Catholicism in the Non-European World

Until the sixteenth century Roman Catholicism was co-extensive only with western and central Europe. During the Age of Discovery, religious orders, always the church's pioneers in evangelization, reached out to the far corners of the world. The first missionaries to the Americas, Africa, and Asia were the Franciscans and Jesuits, soon joined by Augustinians, Dominicans, Carmelites and others. As early as 1622 the papacy set up the Sacred Congregation for the Propagation of the Faith. In the nineteenth century the older orders were augmented with new ones, such as the Missionaries of Africa and the Missionaries of the Divine Word, orders formed specifically for work in the non-Western world. Consciously or unconsciously, these missionaries were conduits for the expansion of important elements of the Western world.

Catholicism achieved its greatest success in Latin America (Spanish and Portuguese America). From its earliest settlements in the Americas, the Spanish crown had a papal mandate to Christianize the lands it colonized. Beginning in 1573 Spain established *la mision*, whereby the native Indians were placed under

the direct care of missionaries, protected by Spanish troops. Most missions flourished, notably the Jesuit Reductions of Paraguay and the Franciscan missions of California and the U.S. Southwest. The native peoples adopted not only the religion of the Spanish but also their language, culture, and occupations. As a result, native culture was all but obliterated, and inhumane treatment of the Indians occurred, despite government regulations to the contrary and the strong defense of the Indians vocalized by such missionaries as the Franciscan Junipero Serra and the Jesuit Pedro Claver.

Spanish rule ended early in the nineteenth century, but the church and especially the hierarchy retained its dominant role in society. As the masses gradually became estranged from the church because of its wealth, anticlerical legislation was enacted in many of the Latin American states. The church-state quarrels ended in separation of church and state, although restrictive legislation if not persecution persisted in many countries, notably Mexico.

Catholicism had to contend with internal dissension as well as external hostility. From the 1960s to the end of the century, liberation theology divided the church. According to this theology the church's primary obligation was to improve the socioeconomic status of the masses. Liberation theology encountered the opposition of both Latin American and Vatican prelates, who contended that it was too sympathetic to Marxist models and that its base communities ("the popular church") were anti-institutional.

The history of Catholicism in Brazil, originally a Portuguese possession, does not differ radically from that of Catholicism in Spanish America, although the Brazilian brand of Catholicism had a greater admixture of ancient heathen elements. From the first Portuguese settlements in the sixteenth century, Franciscans and Jesuits preached the Gospel, at the same time building churches and establishing schools and charitable institutions. Catholicism prospered especially between 1680 and 1750. Decline followed when the anticlerical ministry of the Marquis of Pombal expelled the religious orders. The missionaries were readmitted in the nineteenth century, but the

emergence of an independent Brazil and the subsequent disestablishment of the church under the Republican constitution of 1889 prevented attempts to recoup previous losses. In the twentieth century recurring economic crises and military governments further hampered advances in the Catholic Church. Liberation theology was embraced by many churchmen as a way to end the socioeconomic injustices that plagued Brazilian society, but, as elsewhere, this theology had to be jettisoned. In the early years of the twenty-first century, some 75 percent of Brazilians continued to call themselves Roman Catholics, giving Brazil the largest Catholic population in the world. Latin America as a whole had the largest block of Roman Catholics in the world: 473 million. The monopoly held by the church in this part of the world, however, has been threatened by the inroads of Protestantism, especially evangelical Protestantism from the United States, as well as urbanization, consumerism, and globalization.

In North America, New France (Canada) became Catholic owing in large measure to the zeal of the Franciscans and Jesuits who accompanied the French colonizers and established a real bond with the natives. When France surrendered Canada to England in 1763, it was with the assurance that the rights of the Roman Catholics would be protected. The church continued to flourish; by 2000, about 45 percent of the population was Roman Catholic.

In the United States Roman Catholicism was first introduced by the Spanish missionaries in the areas controlled by Spain, such as California in the West and Florida in the East. In English colonial America Catholicism grew from a small group of English Catholics who settled in Maryland in 1634. The American Catholic Church was strongly committed to separation of church and state. Annual episcopal conferences dealt with problems peculiar to the American environment, such as the assimilation of immigrants, trusteeism, and the threat presented by nativism. Lay Catholic generosity and the labors of religious orders, especially female orders, contributed to the success of

the church. By 2000 it was the largest religious body in the United States.

Roman Catholicism can be said to have achieved only moderate success in Africa. North Africa was solidly Muslim when the Europeans first sought settlements in Africa. Missionary activity in central and southern Africa was initiated by the Portuguese in the sixteenth century. The advent of the slave trade and intertribal warfare were serious obstacles to the evangelization of the Portuguese outposts. By the mid-nineteenth century, as European imperialistic rivalry heated up, most of the natives who had been converted had reverted to paganism. Another wave of evangelization began with the White Fathers in the last quarter of the nineteenth century. Large areas of the Congos (French and Belgian) were converted, as well Uganda. Military coups, tribal warfare, in which Catholics of one tribe slaughtered Catholics of another tribe, and Cold War politics all had devastating results for Catholic churches. Vatican II was a mixed blessing for the African churches. On the one hand it led to a hierarchy that was almost entirely African and it also provided Mass in the vernacular, with the addition of traditional singing and dancing. On the other, the prelates who replaced the Europeans tended to be more conservative, and the downplaying of sacramentals, such as medals and holy water, eliminated a previous point of contact with traditional religions. By the beginning of the twenty-first century, Catholics comprised about 16 percent of the total African population. These Catholics were to be found mostly in Angola, the Democratic Republic of the Congo (former Belgian Congo), the Republic of the Congo (former French Congo) and Uganda. Noteworthy in the history of African Catholicism is the general lack of acculturation as well as deviation from Roman Catholic norms in various areas, such as priestly celibacy, monogamy, and mixed marriages.

In Asia the greatest success of Roman Catholicism was achieved in the Philippines, where Catholicism was introduced by Governor Miguel de Legazpi and

the Augustinians in 1565. Through the friars (Augustinians, Franciscans, and Dominicans) and the Jesuits, Spanish culture was easily transplanted to the Philippines, encountering resistance only in the southern islands, where Islam had been established since the fourteenth century. The Spanish missionaries taught the natives better agricultural and horticultural techniques, introduced arts and crafts, and strongly influence architecture. Respectful of Philippine traditions, they produced some excellent studies of Philippine history and culture. No attempt was made to suppress Tagalog, one of the major languages of the islands. Despite difficult times brought on by decades of foreign occupation (American and Japanese), dire poverty, and terrorist organizations, Catholicism was the religion of 83 percent of the population as of 2008.

Little headway was made by Roman Catholicism in the rest of Asia: Roman Catholics numbered less than 3 percent of the total Asian population as the twenty-first century opened. The main reason for the failure of Roman Catholicism to make inroads in countries such as China, Japan, and India was that missionaries encountered ancient and proud civilizations that made the missionaries seem culturally inferior as well as possible political threats. A contributory factor was the failure of papal authorities to allow the missionaries sufficient flexibility in dealing with Asian religions until it was too late.

A survey of Roman Catholicism in the non-European worlds indicates that it was very successful in Latin America, moderately successful in Africa, and

except in the Philippines, a failure in Asia. The degree of implantation of Western culture varies with time and place.

Roman Empire

The Roman Empire refers to the post-Republican phase of ancient Roman civilization following the rise of its first emperor, Augustus, in 27 BCE. With its power centered in ancient Rome, the empire reached its greatest extent under Trajan around 117 CE, when it took in all of the lands around the Mediterranean, the Black Sea, Mesopotamia, and extended into Britain.

Originating as a conglomeration of small pastoral communities scattered across seven neighboring hills along the Tiber River of Italy, Rome grew to become the capital of an empire that encompassed all the territories bordering on the Mediterranean Sea, extending from the British Isles to the Arabian Peninsula. Roman imperial authority combined the exercise of political and economic dominance with cultural and ideological sovereignty, enforced through strength of arms. The concept of “empire” in English-language usage ultimately derives from the Latin word *imperium*.

The Roman Republic

According to legend, the city of Rome was founded by Romulus and Remus, twin sons of the war god Mars, on 21 April 754/753 BCE. Archaeological evidence indicates that the site was occupied by pastoralists and farmers as early as 1500 BCE but not urbanized until the sixth century BCE under the influence of cities to the north (established by the Etruscans in the area now known as “Tuscany”) and to the south (founded by Greek colonists in southern Italy and Sicily). Originally unified under an Etruscan king, the indigenous Latin-speaking inhabitants of Rome had established

their city as a republic about 500 BCE. The republic’s basic law code, the Twelve Tables (451/450 BCE) defined and guaranteed the fundamental rights and responsibilities of all citizens, but the institutional structures of the state continued to evolve down to about 300 BCE.

The senior magistrates of the Roman republic were the two consuls, elected annually and given chief executive power in civil and military matters, including the command of Rome’s armies. Other annually elected officials in the republic included the praetor, who supervised the administration of justice; the quaestors, who oversaw the state’s finances; and the aediles, who maintained public order and the city’s infrastructure (markets, trade, roads, sanitation, and state-sponsored public entertainments). Every five years two censors were elected to take a census of the entire citizen population and its possessions and to organize any major allocations of the state’s resources that might be necessary. Of these allocations, the distribution of public lands and the construction of new public buildings were the most important.

The censors were also responsible for overseeing the membership of the Senate, appointing new senators, and removing infamous ones from office. The Senate embodied the supreme authority of the Roman state, supervised and disciplined the actions of the magistrates, and possessed ultimate jurisdiction over domestic legislation and the state’s foreign relations.

The Senate and executive offices were dominated by the patricians, Rome’s hereditary elite. The ordinary citizens, or plebeians, were largely excluded from executive power but exercised a voice in public affairs through their membership in one or both of two citizen assemblies. The centuriate assembly

Plan of Pompeii.
Archaeological excavation of the buried city provided much valuable information about life in ancient Rome.

encompassed all citizens whose material wealth was sufficient to require them to provide military service to the state. This electoral body voted for consuls, praetors, and censors. The tribal assembly included all free citizens and voted for quaestors and aediles. This assembly elected its own leaders, the tribunes, who represented the interests of the plebeians in state affairs and came to wield considerable power. The tribal assembly also had the right to propose, deliberate, and vote on new legislation, although such legislation had to be ratified by the Senate.

From Republic to Empire

From its inception the Roman republic was a society prepared for war, with all eligible male citizens expected to bear arms for the state. The Senate had the power to appoint a dictator, an official who would wield absolute power in the state for up to six months in order to see it through a severe crisis, usually violent in nature. The wars during the early centuries of the republic were mostly defensive, and in 390 BCE an army of Gauls briefly took Rome itself, but during the third century the republic began its expansion into a territorial empire. The entire Italian peninsula south of the Po River had come under Roman dominion by 264 BCE. The three Punic Wars fought between Rome and the empire of Carthage (264–241 BCE, 218–201 BCE, 149–146 BCE) led to the expansion of Roman

military power and political sovereignty beyond the Italian peninsula into both the western and eastern Mediterranean. This expansion, which was virtually complete by 30 BCE, brought wealth to the citizens of Rome and expanded the opportunities of the Roman elite to exercise political power as civil and military authorities in the newly acquired provinces.

The expansion also led to the breakdown of the republic's institutions. As Rome's military commitments expanded, the willingness of its propertied citizens to serve in long campaigns far afield declined. In 107 BCE military service was made voluntary, and propertyless citizens (the *proletarii*) were allowed to enlist. Fighting under a successful general, the poor could achieve at least the possibility of upward economic mobility. Goods distributed by commanding officers to their men included salaries, plunder, gifts, and plots of land parceled out from conquered colonies. Not surprisingly, loyalty to the general replaced loyalty to the state.

As a result, the first century BCE was marked by a succession of civil wars between Roman generals competing for dictatorial power over the state. These wars culminated in the conflicts between Julius Caesar and Pompey (49–46 BCE) and Marc Antony and Octavian (33–30 BCE). These wars were fought across the entire expanse of Rome's empire, from Spain through Italy to Egypt, and ended in the permanent imposition of monarchic rule upon the Roman state.

The Principate

After Julius Caesar had defeated the last supporters of his rival Pompey, the Senate embraced the ensuing peace and made Caesar dictator for life in 44 BCE. Although he was assassinated two months later by patrician conspirators claiming they were defending the constitution of the republic, Caesar's popularity among his soldiers ensured that the period of uncertainty led not to a restoration of rule by the Senate and popular assemblies but rather to a power struggle between two claimants to the command of Caesar's troops and political authority: his lieutenant Marc Antony and his adopted son Octavian.

Open war between the rivals broke out in 33 BCE and ended with the suicide of Marc Antony and his ally Cleopatra, whereas Octavian returned to Rome in triumph. In 28 BCE the Senate appointed him its *princeps* (leader) and in 27 BCE gave him the new title of "Augustus," signifying his supreme authority over the state. These new titles in effect created for Augustus (as Octavian was henceforth addressed) the constitutional power of dictator for life. Although the old institutions and offices of the republic remained in place, Augustus now wielded a permanent sovereignty over all aspects of the state, including the Senate, consuls, assemblies, tribunes, and armies. When he died in 14 CE, Augustus was able to pass on his office to his designated successor, Tiberius (reigned 14–37 CE).

The form of government established by Augustus is known as the "principate." Although the legal authority of the *princeps* was absolute, Augustus and his successors allowed much of the day-to-day administration of the state and its empire to remain in the hands of officers and institutions carried over from the republican period. Under the first two dynasties, the Julio-Claudians (14–68 CE) and the Flavians (69–96 CE), periods of apparent instability did not prevent the system established by Augustus from remaining intact. Despite the excesses attributed by contemporaries to Caligula (reigned 37–41 CE), Nero (reigned 54–68 CE), and Domitian (reigned 81–96 CE), the administrative structures of the principate continued to function in an orderly and effective manner. When a civil war broke out at the end of Nero's reign, each of the rivals claimed the title of "Augustus." No one considered the possibility of eradicating that office.

Overall, the first two centuries of the principate brought the Roman Empire the benefits of peace and material prosperity, reaching an apex under the reigns of Trajan (98–117 CE), Hadrian (117–138 CE), Antoninus Pius (138–161 CE), and Marcus Aurelius (161–180 CE). These emperors ruled over a population estimated at 50 to 70 million, linked together by roads, aqueducts, maritime travel and trade, and a shared imperial culture. Despite the era of general peace and prosperity, a significant portion of that population was decimated by the Antonine plague (165–180 CE), which occurred during the reign of Marcus Aurelius and is reputedly responsible for his death via some form of infection while at his army camp. Named after his family name, Antoninus, and also known as the Plague of Galen after the prominent Roman physician who documented the pandemic, it was brought back to Rome by soldiers returning from campaigns around Seleucia in the Near East. Infecting significant numbers of people across and beyond the boundaries of the empire, the plague is estimated to have wiped out up to one-third of the population in some areas. By some estimates the plague was responsible for as many as two thousand deaths a day and ultimately caused the deaths of millions of Romans. With a mortality rate as high as ten percent, the Roman army was

inevitably and severely affected by the plague. Some see the devastating results of the Antonine plagues as a key turning point in the rise and fall of the Roman Empire.

The two universal languages of the empire were Latin and Greek, and under the principate a large number of the empire's inhabitants spoke both. Much of the inspiration for Roman artistic and literary forms derived from Greek models, whose influence became paramount as soon as Rome first established its military dominance over Greece. The first full blossoming of Rome's cultural achievements coincided with the republic's unraveling during the first century BCE. Many of the finest surviving fruits of Roman literature and architecture, however, were produced under the principate. If the late republic can claim the historian Sallust, the poet Catullus, and the statesman Cicero, the principate can claim, among others, the poets Virgil, Ovid, Horace, and Juvenal; the historians Livy and Tacitus; the philosopher and dramatist Seneca; the essayist and biographer Plutarch; the medical theorist Galen; the astronomer Ptolemy; and the architects of the Colosseum and Pantheon. But if the prosperity of the empire derived in large part from the *Pax Romana* (the peace the Romans succeeded in imposing on the Mediterranean world

and used as justification for their imperialism), it also relied heavily on slave labor, a mainstay of the Roman economy since the conquests of the third and second centuries BCE.

Crisis and Recovery

On 31 December 192 CE, Marcus Aurelius's son and successor Commodus (reigned 180–192 CE) was murdered in a palace coup. He was the first emperor to meet a violent end since Domitian, who was assassinated in 96 CE. Claiming to be the incarnation of Hercules and the most skilled of gladiators, Commodus had emphasized the role of emperor as warrior above any other function of the office. All of the contenders in the subsequent civil war legitimized their claim to the imperial throne through acclamation by the empire's soldiers, each being supported by different contingents of the Roman army. The ultimate victor, Septimus Severus (reigned 193–211 CE), secured his title by presenting himself to the people as a military conqueror. The institutions of the principate gave way to an empire ruled and fought over by competing generals. The results were a marked economic decline, political chaos, and a serious destabilization of the empire's borders.

With military victory now the sole means of legitimating imperial authority, the emperors became substantially more bellicose. Warfare became the norm with the advent of sustained attacks on the empire's borders along several fronts, most threateningly by Germanic peoples along the north and Persians along the east. An emperor's defeat on the battlefield was likely to lead to his assassination, and a victory won by one of his generals proved almost as dangerous. The situation was not conducive to maintaining internal order or external defenses, and both suffered. Among the threats to Rome's territorial integrity, the most dramatic was the revolt of Zenobia, queen of Palmyra. She managed to rule over Syria, Anatolia, and Egypt for several years before being defeated by the emperor Aurelian in 272 CE. The years between 211 CE and 284 CE included a succession of some twenty emperors, averaging four years per reign.

The situation stabilized under the rule of Diocletian (reigned 284–305 CE). Although he came to

power as yet another military strongman, he managed to reorganize and thereby stabilize the structure of the Roman state. The most enduring of his reforms included the division of the empire into eastern (Greek-speaking) and western (Latin-speaking) administrative units, the introduction of centralized planning to the Roman economy, and the dramatic expansion of the imperial household staff into a civil bureaucracy that supplanted the obsolete republican magistracies and served as an effective counterweight to the power of the army. Constantine (reigned 306–337 CE) cemented the success of Diocletian's reforms with two revolutionary innovations of his own. The founding of the city of Constantinople (modern Istanbul, Turkey) provided the eastern half of the empire with a capital that possessed legal and symbolic parity with Rome. The transformation of Christianity, in turn, from a persecuted sect to the object of imperial patronage endowed the emperors with a new source of legitimacy independent of both the army and the

civil bureaucracy. The association of the one God with the one emperor provided an effective justification for the divinely instituted authority of imperial rule.

The reforms of Diocletian and Constantine, which transformed the Roman state legally and institutionally into an absolute monarchy, also brought about cultural revival and economic recovery to a society still suffering from the devastations of the Antonine plague. The theologian Augustine of Hippo, the historian Ammianus Marcellinus, the villas whose archaeological remains dot all the former territories of the empire, the numerous monumental Christian churches that survive intact, and the codifications of Roman law under Theodosius II (reigned 408–450 CE) and Justinian (reigned 527–565 CE) are just a few prominent examples of the artistic, literary, and intellectual accomplishments produced by both pagans and Christians between the fourth and sixth centuries.

The Fall of Rome

In spite of these achievements, the same period included a political fragmentation conventionally labeled “the fall of Rome.” The organization of the empire into administrative halves created, alongside the political divide, an increasingly pronounced linguistic and cultural separation between the Greek east and the Latin west. When a new wave of external invasions commenced during the final decades of the fourth century, the Eastern Roman Empire centered in Constantinople managed to survive. The Western Roman Empire, however, lost its territorial integrity and legal identity during the 400s as Germanic leaders established new kingdoms in Italy, France, England, and North Africa. However, historians have come to prefer to describe this process as a “transformation” rather than a “fall.” The material and intellectual culture of these new kingdoms remained recognizably that of Rome, while their kings borrowed their political ideology, symbols and rituals of rule, and administrative techniques from the Roman emperors. Furthermore many of these kings either descended from or themselves had been generals in the service

of the Roman army (which had relied increasingly on foreign auxiliaries and military officers since the third century). Finally, when the Western Roman Empire ceased to exist as a separate entity after the deposition of Romulus Augustulus in 476 CE, the emperor in Constantinople simply claimed legal authority over the entire Roman imperium for himself and his successors.

The Eastern Roman Empire survived as a sovereign state until 1453, having in the meantime provided a prototype for the revival by the Frankish king Charlemagne of a Roman Empire that endured in western Europe from 800 to 1806. After Constantinople fell, Russian czars and Ottoman sultans each proclaimed themselves successors to the Roman emperors. Their states survived into the twentieth century and thus, in a way, so did the Roman Empire. More significantly, the ideas, symbols, institutions, and laws of that empire have provided models for many other states and governing institutions through the centuries and continue to do so today. This partially explains why politicians, journalists, and scholars can productively use the events of Roman history to illuminate current social and political concerns.

Roosevelt, Eleanor

(1884–1962)

DIPLOMAT AND HUMANITARIAN,
WIFE OF PRESIDENT FRANKLIN D. ROOSEVELT

The unprecedented range of Eleanor Roosevelt's activities, both during her troubled marriage to President Franklin D. Roosevelt and after his death in 1945, made her nearly as controversial a figure as her husband. She was a long-time advocate of liberal causes such as child welfare, housing reform, and equal rights for women and racial minorities.

Anna Eleanor Roosevelt, one of the world's most widely admired and powerful women in her time, was the daughter of Elliott Roosevelt and Anna Hall Roosevelt and the niece of Theodore Roosevelt, the twenty-sixth president of the United States. She grew up in a wealthy family that attached great value to community service. It was, however, a family touched by tragedy. One brother died when Eleanor was nine, and both her parents died before she was ten. Relatives raised her and her surviving brother.

When she was fifteen, her family enrolled her at Allenswood, a girls' boarding school outside London. The headmistress's intellectual curiosity and taste for travel and excellence awakened similar interests in Eleanor. After three years, Eleanor reluctantly returned to New York in the summer of 1902 to prepare for her debut into society that winter. Following family tradition, she devoted time to community service, including teaching in a settlement house on Manhattan's Lower East Side.

Soon after Eleanor returned to New York, Franklin Roosevelt, her distant cousin, began to court her, and they were married on 17 March 1905 in New York City. Between 1906 and 1916, Eleanor gave birth to six children, one of whom died in infancy. Franklin's carefree ways and constant pursuit of fun contrasted

with her serious demeanor, making theirs an odd but fascinating pairing. It also spelled doom for their marriage.

Franklin's decision to enter politics forced Eleanor to take on the job of political wife, first in Albany, New York, and then after 1913, in Washington, D.C. She largely found the seemingly endless social obligations tiresome. America's entry into World War I in 1917 enabled her to resume her volunteer work. She worked for the Navy-Marine Corps Relief Society and the Red Cross. This work revitalized her and increased her sense of self-worth when it was suffering most. Eleanor had discovered that Franklin had been having an affair with her social secretary, Lucy Mercer. Devastated, she offered Franklin a divorce. Knowing it would destroy his political career and possibly cost him his mother's financial support, Franklin refused and agreed to stop seeing Mercer.

The marriage became one of convenience and friendship as it settled into a routine in which both spouses kept separate agendas while remaining respectful of and affectionate toward each other. Their relationship, however, had ceased to be an intimate one. Franklin continued seeing Mercer and others, and, in fact, died in Mercer's company at Warm Springs, Georgia, in April of 1945.

Franklin's determination to remain active in politics after contracting poliomyelitis in 1921 depended upon Eleanor's willingness to help keep his name in front of the public. The work dovetailed well with her desire to work for important causes. She joined the Women's Trade Union League and became active in the New York state Democratic Party. She began studying the Congressional Record and learned to evaluate voting records and debates as a member of

A formal portrait of Franklin D. and Eleanor Roosevelt with Anna and baby James, Hyde Park, New York, 1908. Franklin Delano Roosevelt Library, National Archives.

the Legislative Affairs Committee of the League of Women Voters.

When Franklin became governor of New York in 1929, Eleanor found an opportunity to combine the responsibilities of a political hostess with her own interests in social causes. The couple's time together in the governor's mansion left her well prepared for her new role after Franklin's election as president of the United States in 1932. Her twelve years as first lady challenged the prevailing attitudes of the day about a woman's role in a marriage and her place in the political process. Serving as Franklin's "eyes and ears," she traveled throughout the nation giving speeches and providing feedback to the president on the public's opinion on programs and social conditions.

The unprecedented range of Eleanor's activities and her advocacy of liberal causes, such as child welfare, housing reform, and equal rights for women and racial minorities, made her nearly as controversial a figure as her husband. In 1939, when the Daughters

of the American Revolution refused to let Marian Anderson, an African-American opera singer, perform in Washington's Constitution Hall, Eleanor resigned her membership in the organization and arranged to hold the concert at the nearby Lincoln Memorial. The event turned into a massive outdoor celebration attended by seventy-five thousand people. Her defense of the rights of African Americans, youth, and the poor helped to bring groups that had formerly been alienated from the political process into the government and the Democratic Party.

Eleanor instituted regular White House press conferences for women correspondents. Wire services that had not formerly employed women had to do so in order to have a representative present to cover the newsworthy First Lady. Beginning in 1936, she wrote a daily syndicated newspaper column, "My Day," and continued it until just a few weeks before her death in 1962 from a rare form of tuberculosis. After Franklin's death in 1945, President Harry S. Truman appointed her a delegate to the United Nations, where she served as chairman of the Commission on Human Rights (1946–1951) and played a major role in the drafting and adoption of the Universal Declaration of Human Rights in 1948. She remained active in the Democratic Party, working for the election of Democratic presidential nominee Adlai Stevenson in 1952 and 1956.

In 1961, President John F. Kennedy appointed her chair of his Commission on the Status of Women, a position she held until shortly before her death. She had not initially favored the Equal Rights Amendment, saying it would actually do more harm than good for women, but she gradually embraced it. While working for the United Nations and for President Kennedy, Eleanor circled the globe several times, meeting with most of the world's leaders. All the while, she continued to write books and articles. Her work during her White House years and after set a standard by which her successors would be judged.

Roosevelt, Franklin Delano

(1882–1945) THIRTY-SECOND PRESIDENT OF THE UNITED STATES (1933–1945)

Both beloved and hated during his presidency (in office 1933–1945), Franklin Roosevelt expanded the powers of the U.S. government, instituted a number of regulations and reforms to give Americans a “new deal,” and helped preserve Western liberal democracy by aiding Britain during World War II, which created a bulwark against later Soviet aggression.

As the only child of James and Sara Delano Roosevelt, a noted, wealthy family, Franklin had a privileged, sheltered youth. While a student at the exclusive Groton School in Massachusetts, Franklin developed a sense of social responsibility. He graduated from Harvard University in 1904 and then attended Columbia Law School, where he was indifferent about grades. He dropped out of law school upon admission to the New York bar in 1907 and worked three years for a Wall Street law firm.

Personable and outgoing, Franklin married a distant cousin, the shy Anna Eleanor Roosevelt, on 17 March 1905. Her uncle, President Theodore Roosevelt (also Franklin’s cousin), gave the bride away. They had six children, one of whom died in infancy. The Roosevelts stayed active in New York social circles but at the same time devoted considerable energy to the plight of the less fortunate. Although a Democrat, Franklin admired the progressivism of his cousin Theodore and decided early upon a political career. He started by winning a seat as a Democrat in the New York state senate in 1910.

Roosevelt quickly built a reputation as a reformer by taking on the state’s Democratic political machine. For his support of Woodrow Wilson at the hotly contested 1912 Democratic National Convention,

Wilson appointed him assistant secretary of the navy. Roosevelt served from 1913 to 1920 and gained considerable administrative experience. The Roosevelt name and his progressive image won him the party’s vice-presidential nomination in 1920 on the ticket with the conservative Ohio governor, James M. Cox. Roosevelt mounted a vigorous campaign defending Wilson’s advocacy of U.S. membership in the League of Nations. The Democrats were soundly defeated, but Roosevelt never lost sight of the ideals behind the League.

In 1921, Roosevelt contracted poliomyelitis and permanently lost the use of his legs. Although he could have retired to the family’s Hyde Park, New York, estate, he refused to give up his aspirations for public office. Supported by Eleanor and others, he made his return to politics at the 1924 Democratic National Convention with a well-received speech called the “Happy Warrior” and won the New York governorship in 1928 by a narrow margin. His governorship drew on the progressive tradition of his cousin. Its accomplishments included the development of public power, civil-service reform, and social-welfare measures such as relief for the unemployed. Reelected by an overwhelming margin in the 1930 gubernatorial election, Roosevelt soon emerged as a viable opponent to run against the politically vulnerable Herbert Hoover in 1932. By capturing both the Southern and the progressive party elements of the Democratic Party, Roosevelt won the party’s presidential nomination and pledged to give the American people a “New Deal.”

In July 1932, Roosevelt’s Brain Trust, a group of advisors recruited from New York’s Columbia University, assembled to examine the causes and remedies of the Great Depression. Free from the pressures of

First of all, let me assert my firm belief that the only thing we have to fear is fear itself—nameless, unreasoning, unjustified terror which paralyzes needed efforts to convert retreat into advance. • **Franklin D. Roosevelt (1882–1945)**

Franklin D. Roosevelt and Eleanor Roosevelt en route to Washington, D.C., 8 November 1935. Franklin Delano Roosevelt Library, National Archives.

a political campaign, they began planning new government programs to help ease the economic burden in the face of economic collapse. Although he provided no specifics about the New Deal, Roosevelt did discuss conservation, relief, social insurance, and cheaper electricity. Given a choice between the grim, dour Hoover and an exuberant, confident Roosevelt, Democratic voters gave Roosevelt an overwhelming victory in November.

Roosevelt's New Deal program consistently made agricultural recovery and conservation top priorities. The Civilian Conservation Corps and other land management agencies restored lands ravaged by erosion and built recreation facilities in the national parks and forests. The Tennessee Valley Authority, which brought cheap electrical power to millions, focused on improving the living and working conditions of

folks living in that area. In addition, the New Deal sought to rationalize the business system by temporarily ending bitter economic warfare through the National Industrial Recovery Act and its fair practice codes. The New Deal also ended child labor and introduced unemployment insurance and a social security program that guaranteed income for retired Americans. It encouraged the growth of industrial unionism and national legislation to define maximum hours and minimum wages.

Not everyone supported his programs. Emergency expenditures for relief poured millions into the economy, leading to record federal deficits even though he had promised a balanced budget. If Congress or the courts balked at his programs, he used his executive powers to enact them. Some accused him of introducing a socialist agenda or of undermining free-market capitalism. He deflected the criticism well enough to win a record-breaking four terms.

In the 1930s, economic recovery took precedent over foreign policy. Nevertheless, the president sought to improve relations with Latin America through his Good Neighbor Policy. He had hoped to keep the United States out of World War II, which began in Europe in September of 1939, but when the New Deal began winding down, he turned his attention to foreign affairs. Adolf Hitler's stunning victories in Western Europe prompted Roosevelt's decision to seek a third term in 1940. Gradually he moved the United States towards a war footing through various programs to arm Britain and the Soviet Union. The Japanese attack on Pearl Harbor on 7 December 1941 and Germany's declaration of war the next day ended American neutrality.

During World War II, Roosevelt and British prime minister Winston Churchill personally determined Allied military and naval strategy in the West. To prevent a repeat of the problems after World War I, Roosevelt insisted on an unconditional surrender. He relied a great deal on the powers of personal persuasion, believing that he could control Soviet leader Joseph Stalin and foster Soviet-U.S. cooperation through a newly created United Nations. Instead, after the war Stalin imposed Soviet-style communist

American and Allied leaders at an international conference during World War II. National Archives.

governments throughout Eastern Europe. The strain of wartime leadership sapped Roosevelt's health. He died on 12 April 1945 of a cerebral hemorrhage.

Both beloved and hated during his presidency, Franklin Roosevelt transformed the nation by expanding the powers of the federal government. In the face of the potential collapse of the capitalist system, Roosevelt ushered in the welfare state, in part by managing the economy in order to achieve publicly determined ends. By aiding Britain in World War II, he helped preserve Western liberal democracy and created a bulwark against later Soviet aggression. In the process, he converted the Democratic Party to majority status through its appeal to urbanites, minorities, and working-class voters, and made it the party of liberal reform in the twentieth century.

Rubber

Between 1760 and 1940 rubber was converted from a trivial curiosity into a major international industry. It has become central to modern living and crucial to the waging of war. This transformation was not the result of a single breakthrough or even efforts in one country, but was the outcome of a gradual accumulation of technical advances and commercial developments across the world.

Rubber latex, obtained by cutting the bark of certain trees, was used in Central and South America for some fifteen centuries before the arrival of Christopher Columbus. It was made into balls and rubber shoes. Although Columbus and subsequent explorers saw these rubber balls, they did not see this strange material as having any significance. The French scientist Charles de la Condamine, who came across rubber during an expedition to Peru in the 1730s, was the first to suggest the potential uses of rubber such as waterproofed cloth. He called it *caoutchouc* (from the native name *cahuchu*, meaning “weeping wood”). François Fresneau, a French engineer who had lived in Cayenne, French Guiana, also promoted the use of rubber and discovered the value of turpentine as a solvent for rubber in 1763. The first important use of rubber (dating from 1769) was the removal of pencil marks. Rubber-coated cloth was crucial to the development of balloons in the 1780s and 1790s, and suspenders were being made by 1803. There were two important breakthroughs in the 1820s. The English businessman Thomas Hancock invented the masticator, which allowed better processing of rubber, in 1820, and he continued to revolutionize the industry for over two decades.

Meanwhile the Scottish chemist Charles Macintosh replaced Fresneau’s turpentine with a hydrocarbon solvent obtained from coal tar in 1823 and used the rubber solution as glue between two layers of cloth. This waterproof material produced a superior raincoat that soon became known as a mackintosh. In 1834, Hancock and Macintosh joined forces to form Charles Macintosh & Co. in Manchester; it became the leading rubber company in the world.

The Vulcanization of Rubber

Despite the efforts of Hancock and Macintosh, rubber was still a problematic material in the 1830s. In cold weather rubber (and rubberized cloth) became rigid, and in very hot weather it was sticky and could even melt. The American inventor Charles Goodyear (1800–1860) found the answer to these problems in 1839. He heated rubber with sulfur and white lead (which accelerated the reaction) to produce a harder material which could withstand changes in temperature. The process, which Goodyear called vulcanization, after the Roman god of fire, was then copied by Hancock, who improved the procedure. The extent to which Goodyear was indebted to the earlier work of Nathaniel Hayward and the morality of Hancock’s conduct remain controversial even today. However it came about, vulcanization laid the basis of the modern rubber industry. At first the uses of vulcanized rubber were relatively mundane, such as boots, overshoes, and air beds. Ebonite, a hard material produced by prolonged vulcanization of rubber, was important as an early plastic, used to make boxes and jewelry.

Rubber became an important material only after the development of the pneumatic tire by the Scottish

House of a wealthy rubber collector along the Madeira River, a tributary of the Amazon in Brazil.

veterinary surgeon John Dunlop in 1888. Dunlop reintroduced the pneumatic tire (it had originally been patented by the Scottish engineer Robert William Thomson in 1846) with the bicycle in mind. In 1895, Edouard and André Michelin took the important step of adapting their bicycle tire to the automobile, thereby establishing the major use of rubber in modern society. Nearly all of the leading rubber companies were founded in this period, including B. F. Goodrich (1880), Dunlop (1889), Michelin (1889), U.S. Rubber, formed by a merger of older firms and later renamed Uniroyal (1892), Goodyear, which had no connection with Charles Goodyear (1898), and Firestone (1900). By 1910, Akron, Ohio, had become the center of the American tire industry.

Rubber in the Far East

When the Michelin brothers invented the automobile tire, the sole source of rubber was tapping of wild trees in the Amazon River basin. The increased demand for rubber for bicycle tires was an economic bonanza for the Amazonian rubber traders, symbolized

by the lavish opera house at Manaus, Brazil, built in 1896. It was, and remains, impossible to establish rubber plantations in the Amazon basin because of the leaf blight that attacks rubber trees there if they are grown close together, yet the harvesting of rubber from wild trees alone was clearly unsustainable. The solution was the development of plantations in Malaya and the Dutch East Indies (now Indonesia). The British government had established plantations in Ceylon in the late 1870s by buying seeds in Brazil (the popular myth that they were smuggled out is incorrect), but the real breakthrough was the planting of rubber trees in Malaya in the late 1890s, following a fall in the price of the leading cash crop, coffee.

Synthetic Rubber

The industrial synthesis of this important natural material was a bold undertaking and took many years to attain success. The first synthetic rubber was made by the English chemist William Tilden in 1882, but it was not economical since it was made from turpentine, which was both expensive and relatively scarce.

An encyclopedia drawing summarizing all one needs to know about rubber, an important raw product during the colonial era.

When rubber prices were high in 1910, attempts to produce synthetic rubber were pursued in England, Germany, Russia, and the United States. The most successful was Bayer's "methyl rubber," made from acetone, which was used by Germany as a rubber substitute during World War I. Interest in synthetic rubber revived in 1925, as the result of an attempt by the British government to restrict exports from Malaya and Ceylon, and synthetic rubber production was started in the Soviet Union, Germany, and the United States in the 1930s. The Soviet industry made a weak synthetic rubber (polybutadiene) from ethyl alcohol and set up the first synthetic rubber factories at Yaroslavl' and Voronezh in 1932. By 1940 production had reached 40,000 to 50,000 tons. The German firm I.G. Farben (formed by a merger of Bayer with BASF and Hoechst in 1925) developed a new class of synthetic rubber called copolymers, one of which turned out to be suitable for tires, while another was oil-resistant and was used for gaskets and gasoline

hoses. When the Nazis came to power in 1933, they were keen to use these synthetics as a substitute for natural rubber. Within ten years, I.G. Farben had erected three factories and Germany was producing thousands of tons of synthetic rubber. After the war ended, information from the German plants (and deported chemists in the case of the Soviets) assisted the technical development of the American and Soviet industries.

Initial attempts to create an American industry faltered, but progress was rapid when America was cut off from the Far Eastern plantations after Pearl

Harbor. Most of the U.S.-produced synthetic rubber, manufactured under government control and called GR-S (Government Rubber–Styrene), was petroleum-based, but some of it was made from maize-based ethyl alcohol to appease the vociferous farm lobby. The decision to keep most of the plants open after World War II was vindicated by the outbreak of the Korean War in June 1950, which was preceded by a rapid increase in the price of natural rubber. The technical improvements introduced during this period, polymerization at lower temperatures and addition of mineral oil, made GR-S competitive with natural rubber. As a result, the industry was privatized by Congress between 1953 and 1955.

The Modern Rubber Industry

West Germany adopted the American petroleum-based technology for synthetic rubber in the early 1950s. Over the next decade, synthetic rubber factories were established in Britain, Italy, France, Japan, and even Brazil, the original home of natural rubber.

Synthetic rubber overtook natural rubber around 1960. The American synthetic rubber industry maintained its leading position, despite growing competition from Japan. In tire manufacture, however, the Americans had failed to realize the importance of the radial tire, which had been introduced by Michelin in 1949.

The oil crisis of 1973 had a severe impact on the American industry. Its synthetic rubber production was hit by the quadrupling of the price of its raw material, oil. Radial tires (which can only be made from natural rubber) reduced fuel consumption of automobiles and sales soared in the 1970s, but then Firestone's radial tires were shown to be unsafe and had to be recalled. In the 1980s, all the plants in Akron were closed, Goodrich and Uniroyal merged their tire businesses and then sold the joint operation to Michelin, and Firestone was taken over by the Japanese firm Bridgestone. Since the oil crises of the 1970s, natural and synthetic rubbers have settled into an uneasy but enduring co-existence. It now appears unlikely either form will disappear completely. Whatever form it takes, rubber will continue to be important as long as we use automobiles, take flights, or just walk along the road.

Rumi

(1207–1273)

PERSIAN POET

The poems of the thirteenth-century mystic Rumi—who lived in what is now Turkey and wrote in Persian—preached ecumenism, compassion for one’s fellow being, and tolerance. The Mevlevi Sufi order of dervishes founded by Rumi danced and sang his verses and thus achieved ecstatic encounter with God. His works, translated into many languages, continue to inspire those in the Islamic heartland and beyond.

Jalal ad-Din ar-Rumi, known as Mevlana—the Turkicized form of the Arabic word *Mawlana*, which means “our master”—is one of the best-known figures of Muslim spirituality and devotional poetry worldwide. He established his own Sufi order, known as the Mevlevi, in honor of its founder. The Mevlevi Sufis (popularly called the Whirling Dervishes in the West) are based in Konya, Turkey, where Rumi lies buried. The order is distinguished by its special rites, which include music and a special whirling dance, designed to foster intense contemplation of the Divine Beloved (God).

Rumi was born in Balkh in present-day Afghanistan. His father was a well-known jurist, preacher, and Sufi mystic who combined knowledge of both the exoteric sciences, such as law and hadith studies, with the esoteric sciences, such as the study of spiritual techniques and practices. When Rumi was about twelve years old, his family fled Balkh in fear of the Mongols, who were drawing close to the city. They traveled through a considerable part of the Muslim world on their way to Mecca, and after performing the pilgrimage there, settled in Konya, where they were received warmly by the Seljuk ruler.

Rumi was given a sound Islamic education that stressed knowledge of the Qur’an, hadith (sayings of the Prophet Muhammad), Arabic grammar, religious law, principles of jurisprudence, Qur’an commentary, history, logic, philosophy, mathematics, and astronomy, among other subjects. From his father he also became acquainted with the practices and techniques of Sufism, albeit informally.

In 1231, when Rumi was twenty-four, his father passed away. Rumi, already recognized for his considerable learning, inherited his father’s position as professor in religious studies and preacher to the people of Konya. In 1232 the Sufi Burhan al-Din Tirmidhi who had been a disciple of Rumi’s father, moved to Konya, and Rumi began to receive formal training in the mystical ways of Sufism. Rumi’s association with Tirmidhi continued until the latter’s death in 1240.

For the next four years, Rumi continued his activities as a preacher and as a doctor of law in the Hanafi School of Islamic jurisprudence, gaining widespread renown for his erudition. He also continued his Sufi practices, becoming a master in his own right, which means that he traversed the various stations of the Sufi path and attained the mystical vision of God. His Sufi practices appear not to have had much effect on his outward life as a conventional scholar, jurist, and religious counselor to his people.

All this was to change in 1244 when a charismatic and mysterious individual by the name of Shams al-Din of Tabriz, popularly known as Shams-i Tabrizi, arrived in Konya and entered Rumi’s life. Rumi described the transformative aspects of this fateful encounter in his poetry:

Rumi's teacher, Shams-i Tabrizi, portrayed in an illustrated copy of Rumi's poem, the "Diwan-e Shams-i Tabriz-i," circa 1502–1504. Bibliothèque Nationale de France.

I was the country's sober ascetic, I used to teach from the pulpit—but destiny made me one of Thy hand-clapping lovers; My hand always used to hold a Koran, but now it holds Love's flagon; My mouth was filled with glorification, but now it recites only poetry and songs! (Chittick 1983, 3)

Rumi became inseparable from Shams as a friend and spiritual disciple. One prominent scholar said of Shams's influence on Rumi: "(H)e was transformed from a sober jurisprudent to an intoxicated celebrant of the mysteries of Divine Love. One could say that without Shams, there would have been no Rumi" (Chittick 1983, 3). This is only slight exaggeration;

the world might well have been deprived of what is now considered to be among the best-selling poetry of all time if the two had never met.

Roughly in the year 1247, Shams disappeared, perhaps killed by Rumi's followers, who were jealous of his influence over their master. Rumi was rendered completely bereft at the permanent loss of his beloved master and companion. But although Shams was no longer a physical presence in Rumi's life, he became immortalized as a fixed, phantom presence in the latter's heart and mind. From this year until Rumi's death in 1273, he stopped his public preaching and wrote poetry incessantly, many of which are Persian *ghazals*, or love songs, in which he often speaks of the pain of being separated from Shams. But Rumi frequently invoked the name *Shams* as the representation of the image of God, the Divine Beloved. The word *shams* means "sun"; by its invocation, Rumi referred to both his friend and "the Sun of the Sun," the Almighty who is the true Beloved and the Ultimate Reality.

Among his major compositions are the *Diwan-i Shams-i Tabrizi* (Collected Poems of Shams-i Tabrizi), which consists of about 40,000 *ghazals* and quatrains, and the *Mathnawi* (couplets), which contains roughly twenty-five thousand verses of mostly didactic poetry. Translations of a major part of his oeuvre into several Western languages are available, and they have helped to establish his reputation as a poet and thinker for the ages: one who preached ecumenism, compassion for one's fellow being, and tolerance in his exquisite poems.

Rumi, in fact, has become the best-selling poet in contemporary America, and his poetry continues to inspire traditional Sufis in the Islamic heartlands and beyond, New Age spiritual devotees, and other mystical practitioners in the West in their devotions. The Mevlevi Sufi order founded by Rumi exists to this day and its adherents perform their popular "folk dances" all over the world. Rumi has, furthermore, become a byword in certain circles for a tolerant, compassionate Islam that serves as an urgent antidote to the more militant version that dominates

the news today. Such a multifaceted legacy is a testimony to humanity's exceptional gift for addressing basic concerns in an accessible yet eloquently profound idiom.

Russian Soviet Empire

With the Mongols in decline by 1480, Ivan III declared himself Sovereign of All the Russias. His successors became “czars” (from “Caesar”) and Moscow the “third Rome”—thus the Russian Empire was born. Continued territorial and economic growth generated counter pressures that led to the empire’s undoing by 1900—until the Communist era and the emergence of the USSR as a superpower in the second half of the twentieth century.

The Russian Empire has its origins in the rise of the Principality (*kniazhestvo*) of Moscow in the fourteenth and fifteenth centuries. The Muscovite Grand Princes successfully exploited their position as tax collectors for the Golden Horde, which ruled most of Russia in the wake of the Mongol conquest in 1240, to impose their authority over the successor states to Kievan Rus. By the early fifteenth century, Mongol power had begun to decline. At this time, Moscow emerged as the champion of Orthodox Christianity (the official religion of Kievan Rus since 988) and outmaneuvered Catholic Lithuania to legitimate itself as the “gatherer of Russian lands.” After 1480, Grand Prince Ivan III (reigned 1462–1505) ceased paying tribute to the Khan and proclaimed himself Sovereign of All the Russias. (Ivan had also seized upon the collapse of Constantinople in 1453 by marrying the last heiress to the Byzantine throne.) His successors were increasingly referred to as czars (derived from *Caesar*), while Moscow was proclaimed the “third Rome” and became the center of the Orthodox Christian world.

Henceforth, the czar would regard himself as a universal ruler, on a par with the Ottoman Sultan or

the Holy Roman Emperor. After the conquest in the 1550s of Astrakhan and Kazan—successor states to the Golden Horde—the czars also began to claim the descent from the Chingizid Khans, the dynasty of Chinggis (Genghis) Khan. They used the popular image of Mongol rule as arbitrary and beyond divine sanction to great effect in the imposition of autocratic rule over the whole of Russian society, although the roots of their despotism lay largely in the difficulty of extracting a sizable surplus, given the country’s poor soil and difficult climate. Autocracy reached an apogee with the establishment of the Oprichnina (literally “setting apart”), a policy that imposed the Czar’s unbridled terroristic rule over a quarter of the country and (to Ivan’s mind) constituted a model for the whole of Muscovy. All these factors have led many writers to conclude that Russian rule was a classic example of “Oriental despotism,” whose fundamental essence would remain unchanged through the Soviet period.

Autocracy and Isolation

In the sixteenth and seventeenth centuries, the Muscovite realm formed, by and large, a world unto itself—to some, a quintessentially Eurasian civilization. The disintegration of the Mongol-dominated system of the thirteenth and early fourteenth centuries resulted in a diminution of contacts and the growth of regional particularisms across Eurasia. Muscovy’s frontiers were not coterminous with those of any other core area, and its espousal of Orthodoxy greatly limited its exposure to the culture of proximate Muslim or Catholic powers. In the wake of Ivan the Terrible’s failure to push through to the Baltic Sea in the

Livonian War (1558–1583), the economic and demographic dislocations of the Oprichnina, and the Polish invasion, revolts, and dynastic crises of the “Time of Troubles” (1600–1613), Muscovy contracted. Its detachment was further compounded by the closure of its borders and the restriction of external trade by the Romanov czars of the seventeenth century. Some judge the failure to integrate into Europe at this time as an unmitigated disaster, responsible for the perpetuation of Russian autocracy and backwardness, though others contend that the failed incorporation allowed Russia to preserve political and economic independence. In fact, despite autocracy, the seventeenth century saw the empire attain its fastest rate of growth. Russia took advantage of the collapse of Mongol power to colonize lightly populated Siberia by 1649, and benefited from the decline of Poland by incorporating the Ukraine in 1667. Expansion was stimulated by a crusading mentality that encompassed a desire to win converts for Orthodoxy, as well as recognition of the czar as a universal ruler. But it was driven even more by the fur trade and the desire of marginalized groups—runaway peasants, convicts,

Cossacks, merchants, and religious schismatics—to flee autocratic control. Thus, the czars’ rule over the new Siberian towns, the Ukrainian Cossacks, and nomadic peoples such as the Oirats and the Nogais remained nominal.

An Expanding Empire

The character of the empire was partially transformed during the reign of Peter I (the Great, 1682–1725) and that of his successors. The thrust of the Petrine reforms was making Russia militarily competitive with European powers, but in order for this to be achieved the social and cultural foundations of the autocratic regime had to be altered. Peter introduced a standing army, a civil service, and a European-style technical-scientific infrastructure. On this basis, he eventually won the Great Northern War (1700–1721) against Sweden and gave Russia an outlet to the Baltic coast, where he established his “window on the West”—the new capital of Saint Petersburg. With Russia’s arrival as a European power, the czar now styled himself Emperor, while the country was renamed

History is politics projected into the past. • M. N. Pokrovsky (1868–1932)

from Rus to the Latinized Rossiia. A weakened Orthodox Church no longer constituted the empire's main source of legitimacy, which would now emanate from the manifest destiny to expand and the specifically Russian *mission civilisatrice* of the state itself. But Peter's reforms continued to rely on autocratic means—tributary extraction, mass population transfers, and a newly constituted political police. Subsequent rulers, though they may have freed the nobility (1762), granted the right for the free establishment of industries (1767), liberated the serfs (1861), and permitted the creation of a legislature (the Duma, in 1905), never relinquished their monopoly on political power.

Unlike the empires of western Europe, the Russian Empire was a contiguous and continental power that lacked easily defensible boundaries and therefore pursued a predominately territorialist rather than a maritime strategy. As a result, it pursued expansion in all directions and had to devote an overwhelming part of its state budget to its military. At the same time, Russia remained economically underdeveloped, and some of its colonies—notably Poland (dismembered between 1772 and 1815) and Finland (acquired in 1808)—exhibited greater economic and social sophistication than the Russian core area itself. New Russian territories in the east and south—Crimea (conquered by 1790), the region of Caucasasia (subdued by the mid-nineteenth century), and Turkestan (subjugated between 1850 and 1900)—did resemble European colonies, being administered through a mixture of economic extraction and development, civilizing paternalism, and the cooptation of local elites. Unlike Western possessions, however, they had relatively low populations, relatively more colonial settlers, and displayed far fewer differences in terrain, climate and ecology relative to the metropolitan power.

Because of its greater proximity to Europe, Russia was forced to respond to European military, economic, scientific, and technological innovations earlier, but this in turn accounted for its greater dynamism vis-à-vis other tributary and contiguous empires. The Russian Empire expanded at the expense

of the Ottomans in the Black Sea region and the Persians in Central Asia, and, by the nineteenth century, established hegemony over Chinese Manchuria. Still, its effort to extend its control by incorporating expanding Ukrainian and Belarussian populations—both Orthodox and both heirs of Kievan Rus—into its ethnic core proved less successful than similar efforts by China. The late-nineteenth-century policies of cultural Russification, which affirmed nationality as the third pillar of the regime alongside autocracy and orthodoxy, fared no better than the attempted federalism of the Habsburgs.

Continued territorial and economic growth generated increasing counter pressures that eventually led to the empire's undoing. Externally, its early successes contributed to the rise of more powerful rivals along its perimeter. In the west, Poland and Sweden were replaced by a united German Empire—an industrial powerhouse with a much larger population. In the south, France and Britain propped up the declining Ottoman and Persian empires, while in the east, a vibrant Japan filled the vacuum created by a retreating China. Victory against Napoleon in 1812–1815

This drawing from the late 1800s depicts a Russian peasant family. Although Russia was urbanized and industrialized, the idea of the Russian peasant was a common one throughout Europe.

established Russia as the main guardian of political reaction in Europe, but exposure to the ideas of the French Revolution infected its own elite with a dissident spirit. The humiliating defeats of the Crimean War (1855) and the Russo-Japanese War (1905) exacerbated social discontent, as did the rapid industrialization program pursued under Nicholas II at the turn of the twentieth century. The paradox of Russia as both backward and a colonial power widened its identity crisis. The Westernizer–Slavophile debate ultimately resulted in what some regard as a revolutionary synthesis and others as a dead end.

Communist Rule

Czarism succumbed to the combined pressures of World War I and urban unrest in 1917, but the Bolshevik Party, which came to power in the October Revolution later that year, reconstituted the empire. As Marxists, the Bolsheviks were dedicated to the replacement of the world capitalist system with proletarian democracy, but the practice of “democratic centralism” favored by their leader Vladimir Ilyich Lenin (1870–1924) promoted the Party’s control over and above that of the workers’ councils (soviets) in whose name they governed. During the ensuing Civil War (1918–1921), the Bolshevik base corresponded

to the old Muscovite core (with the capital reestablished in Moscow), and their eventual victory resulted not in worldwide revolution but in the reconquest of the czarist empire (minus Finland, Poland, and the Baltic states). Subsequently, the Bolsheviks focused their attention on Asia and proclaimed Soviet Russia as the global leader of the anticolonialist struggle. In the same spirit, in 1922, they established the Union of Soviet Socialist Republics (USSR), which recognized the formal sovereignty of the non-Russian republics (including the Ukraine, Belorussia, Transcaucasia, and Turkestan), and promoted their cultural autonomy by suppressing overt Russian nationalism. At the same time, central control was cemented by reconfiguring the Bolsheviks as the All-Union Communist Party, and the world’s first “affirmative action empire” came into being (Martin 2001).

The Communist Party’s monopoly on power, coupled with the country’s economic collapse following seven years of war, its international isolation as a socialist state, and the Marxist antipathy to market economics contributed to the USSR turning into a continuation of the Russian Empire. Under Joseph Stalin (1879–1953), who emerged as Lenin’s successor by the late 1920s, the pursuit of “socialism in one country” denoted gaining complete control of the domestic economy following the collectivization of the peasant land holdings, establishing Marxism-Leninism as the guiding ideology of all social and cultural life, constructing a cult of personality, and prosecuting mass purges and population transfers. The autarkic imperative of Stalin’s USSR resembled that of seventeenth-century Muscovy, and authors who characterize the former as a totalitarian state explicitly establish its links with earlier autocracy. Moreover, under conditions of monolithic rule, the heightened international insecurity of the 1930s, and especially the Great Patriotic War (the Russian struggle against the World War II Nazi offensive of 1941–1945), non-Russian elites and, in the case of the Crimean Tartars and Kalmucks, whole peoples were regarded as unreliable, and viciously persecuted, while Great Russian culture and Russification were promoted as important mobilizing forces.

The Novograd monument to celebrate Russia's 1000th anniversary, as photographed between 1860 and 1880.

Postwar Superpower and Beyond

The emergence of the USSR as a superpower in the second half of the twentieth century has led some scholars to regard the Soviet Empire as the culmination of a singularly successful and uniquely Russian alternative modernity. In the 1930s, Stalin oversaw the mobilization of the USSR's vast resources in the construction of a modern industrial base, and in achieving spectacular rates of economic growth. These factors enabled the Soviet Union to defeat Nazi Germany in World War II and subsequently to become a nuclear power and the main strategic competitor of the United States (though a *de facto* junior partner in the American-led world order). In the wake of the war, the USSR reincorporated the Baltics, the western parts of Ukraine and Belorussia, and Bessarabia, and conquered East Prussia.

Its newly acquired string of satellite states in Eastern and Central Europe, organized on the Soviet model, paralleled the more successful East Asian single-party regimes—Japan, Taiwan, and South Korea—constructed at the same time by the United States. Because it had now emerged as a predominantly urban country, its development model likewise proved attractive to many emerging states of the Third World, especially those ruled by native revolutionary movements (Yugoslavia, China, North Korea, Cuba, Vietnam). The Soviet Union also supported non-Communist clients in Africa, the Middle East, and South Asia. Soviet leaders attempted to develop a socialist division of labor within its sphere of influence, although in practice, exchanges often amounted to colonialist underdevelopment (as in cotton-growing Uzbekistan) and transfers of military technology.

Nevertheless, the realities of being an empire in the twentieth century weighed upon the Soviet Union to a much greater degree than its leaders or totalitarian theorists realized. Its success during the Cold War was largely conjunctural—a product of the temporary vacuum created by the wartime destruction in Europe and Japan. The Soviet “command-administrative” system proved incapable of long-term competition with Western and Asian economies under the conditions of “peaceful coexistence” promoted by Stalin’s successors. The stagnation of “socialist development,” partial cultural liberalization, the exposing of Stalinist crimes, and increased contacts with the outside world had the effect of demoralizing Soviet elites and undermining revolutionary legitimacy. By the mid-1980s, military overextension and economic contraction convinced sections of the governing elite that the empire had become prohibitively expensive.

Under Mikhail Gorbachev, who led the nation from 1985 to 1991, an attempt at structural reform (*perestroika*), intended to regenerate economic growth, end the Cold War, and restore faith in the Soviet system instead fully exposed the incompatibility of socialism and empire and transformed the USSR’s composition as a union of nominally sovereign republics into a liability. Gorbachev’s refusal to prop up and subsidize the unpopular Communist governments in Eastern Europe resulted in the revolutions of 1989, which, together with the erosion of Party power and economic chaos in the Soviet Union itself, prompted the rise of powerful secessionist movements in the individual republics, including the Russian Federation itself. In 1991, the new republican presidents dissolved the Union, but the collapse of the Soviet Empire was not welcome everywhere, and, by 2004, new imperial rumblings were evident.

Sailing Ships

For nearly all of human history the most efficient way of conveying goods and people over great distances was by water, especially using wind power harnessed by sails to propel a vessel. Not until the advent of steam-powered ships during the nineteenth century did wind-powered sailing ships cease to be the dominant mode of fast long-distance transportation.

Sailing ships date at least to the ancient Egyptians and Phoenicians, although people probably used smaller sailing vessels earlier. Boats were crafted from reeds, skins, and wood, the earliest form of wooden boats being dugouts. Early sailing ships were built primarily of planks, with the planks either joined end to end by mortise-and-tenon joinery or joined in an overlapping fashion (clinker construction) and fastened by dowels or nails. Sails were made out of woven cloth (cotton, flax, or hemp), although some early Egyptian sails were made from papyrus fibers and other woven grasses. Many early sailing vessels were also outfitted with oars, which provided easier mobility and optional power when wind was absent. Early ships were lateen (square rigged). These methods provided more sail power but less maneuverability than modern rigging with triangular sails. Indeed, until the nineteenth century and the technology that powered ships by steam, using the wind to sail on rivers and seas was the most expedient way to move people (and the goods needed to sustain them) over long distances.

Antiquity–400 CE

Since the mid-twentieth century and the development of underwater archaeology, a huge expansion

in people's knowledge of sailing ships has allowed scholars to study the remains of ships from all periods of history. The earliest archaeological evidence for a water vessel is a birch paddle found at a prehistoric campsite in England from about 6000 BCE. The earliest evidence for a sailing vessel comes from a model sailing raft excavated in Chile. Rafts of logs bound together with a mast and sail were probably the earliest forms of prehistoric sailing watercraft. Skin boats, constructed of animal hides sewn together, were primarily found in northern cultures, particularly the Eskimo, Irish, and northern Russian. Eskimo kayaks and umiaks (open Eskimo boats made of a wooden frame covered with hide) were primarily rowed, although some evidence indicates sail use. Large versions of the Irish curragh, constructed of ox hide, were sailed and took early Irish travelers to the Hebrides, Shetland Islands, and even to Iceland. Reed boats were used primarily in the South Pacific, in the Americas, and among the Marsh Arabs of southern Iraq. Dugout technology is ubiquitous through world cultures, but in the South Pacific large dugouts have outriggers that have sails in addition to oars. Many scholars believe that these sorts of craft made possible human migration throughout the South Pacific.

Plank construction allowing larger ships developed independently in a number of places, including Egypt, England, and China. The earliest evidence comes from Egypt, where vessels were constructed out of cedar planks joined edge to edge but with no internal framing or keel. Because of the unique river conditions of the Nile River, one could float downstream with the current and return under sail upstream. The earliest surviving Egyptian boat, the royal ship of Cheops,

***Canja under Sail*, an illustration from a book about travels to discover the source of the Nile in the eighteenth century.** Schomburg Center for Research in Black Culture / Manuscripts, Archives and Rare Books Division.

dates to 2650 BCE and was excavated in 1954 from a burial pit alongside the Great Pyramid. Many artistic depictions feature Egyptian boats, including seagoing vessels. These depictions invariably show both sails and rowers. Around 1500 BCE Queen Hatshepsut ordered the construction of a fleet of large craft similar to the Nile craft with rowers, a single large mast, and a rudder for a voyage down the eastern coast of Africa. A pictorial account of the voyage remains at a temple in Deir-el-Bahari.

In 1982 researchers found an underwater wreck of an early Levantine (relating to the countries bordering on the eastern Mediterranean) commercial seagoing ship at Ulu Burun off the Turkish coast, dating to 1350 BCE. It was a sturdier craft than Egyptian craft of the time, with a large keel and planks lashed together. Egyptian wall paintings also reveal evidence for Minoan and Mycenaean ships, showing them to be similar in design to Egyptian ships but having only sails and no rowers.

The greatest ancient seafarers, the Phoenicians, sailed ships throughout the Mediterranean Sea, and evidence points to some voyages along the Atlantic coasts of Africa and France. In form, their merchant ships were more similar to Cretan ships than

Egyptian ships, with square rigging and often two banks of rowers. The Greeks developed a specialized high-speed warship, the trireme (a galley with three banks of oars, a sail, and a large battering ram on the bow just at the waterline), which could damage and sink enemy ships. The trireme had a single mast and sails that were square rigged, but during battle rowers were used for maneuverability and control. The Greeks used the trireme at the Battle of Salamis in the Saronic Gulf in 480 BCE, when the Athenians defeated a larger Persian fleet and won the Persian Wars.

Researchers have found Roman merchant ships in abundance in the Mediterranean and Black Seas; more than four hundred wrecks have been identified. Roman merchant ships relied exclusively on sail power and were used to transport all manner of goods, including wine, olive oil, marble, and grain. The majority of merchant ships were single or double masted, with square sails, and sometimes a triangular topsail on the main mast. The second mast, in front of the main mast, was rigged with a smaller steering sail called the *artemon*. These were medium-sized ships that could haul a cargo of around 300 metric tons. Most impressive in the Roman merchant fleet of the first and second centuries CE were the *navis oneraria* (transport ships) that carried grain from Egypt and North Africa to the Roman port of Ostia, sometimes 1,200 metric tons in a single voyage.

The earliest northern European planked boats date from 1217 to 715 BCE. They were relatively small river craft, about 14 meters long, called “Ferriby” and “Brigg” boats. They were discovered in the Humber River in Yorkshire, England, and have a complex, sewn-plank joinery. The earliest Asian evidence of planked construction dates to 50 BCE. The Hjortspring boat, discovered in a peat bog in Denmark, dates to 300 BCE and is constructed of plank with lashings holding the boat together and overlapping strakes (continuous bands of hull planking or plates on a ship). Experts think this boat was a forerunner of the clinker (overlapping plank) Scandinavian craft. All of these vessels exhibit shell-first construction, rather than frame-first construction, which would become the standard during the high Middle Ages.

Junks float majestically in the Huangpu River, Shanghai. Photo by Joan Lebold Cohen.

Byzantine ships continued Greco-Roman building practices, including mortise-and-tenon joinery of the planks, as evidenced by the Yassi Ada shipwreck of the seventh century CE, excavated by George Bass in the 1960s. The earliest known clinker boat, the Nydam boat (310–320 CE), is of northern European origin and is about 23 meters long with a double-ended hull, a feature that the Roman historian Tacitus mentioned as characteristic of Scandinavian boats in the late first century CE. These early Scandinavian boats were rowed rather than sailed; sails were not introduced in Scandinavia until around the seventh century CE. With the introduction of the sail the true Viking age began; Scandinavian sailors traveled throughout the North Sea and Baltic Sea and eventually ventured as far as North America and the Black Sea. The Norman invasion of England in 1066 CE, long after the Viking raids had ceased, was carried out using longboats (large oared boats) in the Scandinavian style.

Beginning during the twelfth century in the northern European towns of the Hanseatic League (a league

originally constituted of merchants of free German cities), a new kind of sailing vessel was created. The cog was a round merchant vessel with high sides, built for hauling cargo. Cogs included high structures called “castles” both fore and aft to house archers or gunners to help protect the ships from raiders. Single masted, square rigged, with a large centerline rudder in the stern, cogs required only a small crew to handle. By the twelfth century inexpensive, machine-sawn planks, made possible by the hydraulic sawmill, replaced split wood planks, and large ships that took advantage of this plentiful supply of planks appeared. Larger cogs were built with more masts, and by the 1400s clinker-plank construction gave way to edge-to-edge planking attached to internal framing.

1350–1700 CE

The Venetian galley, ranging from 39 to 50 meters long, often with two banks of oars and one mast with lateen-rigged sails, dominated the medieval Mediterranean beginning at the end of the ninth century.

Samuel Atkins (1780–1810), *Shipping In Ramsgate Harbour* (n.d.). Watercolor, brown ink, and pencil. The advent of the steamship meant the eventual demise of the sailing ship as a vehicle of trade.

By the fourteenth century Venetians began building “great galleys”—bigger, longer vessels with two masts for commercial and passenger traffic. During the sixteenth century a new Mediterranean ship emerged, the *galliass*, a huge galley designed for warfare. *Galliasses* had both oars and sails and crews of up to seven hundred. Six *galliasses* fought at the Battle of Lepanto in Greece’s Corinthian Gulf in 1571, helping to defeat the Ottoman Turkish fleet. Galleys and *galliasses* also formed part of the Spanish Armada in 1588.

The invention of the carrack during the mid-fifteenth century resulted from the combination of northern and southern shipbuilding influences. Carracks, created in the shipyards of Venice and Genoa, were large modified cogs, with three, four, or even five masts with a variety of sails, both square and lateen rigged. Multiple masts and combination rigging made carracks easy to control and faster than traditional designs. Another innovation was frame-first construction, where planks were nailed to the frame. Carracks were the largest merchant vessels of their time, hauling 362 metric tons, but by the sixteenth century they were hauling 907 metric tons. The English king, Henry VIII, beginning in 1509 built a fleet of “great ships,” including two large carracks. Both ships were heavily armed with artillery, and when the wreck of the *Mary Rose* was

discovered, two thousand arrows in neat bundles were found. Smaller and lighter than the carrack, the *caravel* also appeared during the fifteenth century, probably of Spanish or Portuguese origin. Primarily for commercial use, the *caravel* is known primarily for its use in the great exploration voyages of Christopher Columbus of Genoa, Italy, and Bartolomeo Dias and Vasco da Gama of Portugal.

Growing transatlantic trade during the sixteenth century resulted in the development of oceangoing vessels such as the galleon. Shorter than a galley, not as bulky or heavy as a carrack, the galleon had three or four masts, with both square and lateen rigging. It had high sides and castles for artillery. Large oceangoing sailing ships were also being developed in China as early as the tenth century CE. During the thirteenth century the Venetian traveler Marco Polo reported seeing four-masted merchant ships during his long stay in China. In 1973 a large thirteenth-century ship was found at Houzhou; it was about 35 meters long, with a keel and double cedar planking on the hull. Writings from the Ming dynasty (1368–1644) describe the voyages made between 1405 and 1433 by the eunuch admiral Zheng He in a fleet of nine-masted ships 120 meters long, although researchers have found no such ships. Chinese shipbuilding suddenly ended in 1550 with an imperial ban on overseas commerce.

A sailing ship is no democracy; you don't caucus a crew as to where you'll go anymore than you inquire when they'd like to shorten sail. • **Sterling Hayden (1918–1986)**

The founding of the Dutch East India Company in 1592 propelled the Dutch to the forefront of long-distance trading, eclipsing the Portuguese. The three-masted Dutch flute, a narrow merchant ship that was developed partially to avoid taxation related to the width of the vessel, remained the dominant cargo vessel into the eighteenth century and was soon being built in England, Germany, and Scandinavia. The English and French trading companies, created in response to Dutch maritime power, also owned their own fleets and militia. During the seventeenth century science entered the shipyards, particularly in France, with highly trained naval architects applying mathematics to ship design. Around 1670 the huge castles at the ship's stern began to shrink to reduce weight.

Large naval fleets came to the forefront in warfare during the seventeenth century. The capture of Gibraltar in 1704 by the British was one of the great successes of the British fleet and gave England control of access to the Mediterranean. During the eighteenth century the construction and outfitting of warships took center stage as the rivalry between European powers was waged on the seas through exploration, colonization, and naval battles. In addition to the large warships, battle frigates, adapted from lean, maneuverable commercial vessels, became an important element of the naval fleets of Britain and France.

In 1750 shipbuilders in the British colonies in North America developed an entirely new form, the schooner—a small, fast ship with only two masts that initially was used for fishing and trade. The Revolutionary War brought a military dimension to the schooner, which navies used to conduct merchant raids and run blockades. Later slave traders used schooners between Africa and the Americas, particularly after 1820, when slave trade was outlawed by many world governments. The fledgling navy of the United States began with the commissioning of six such ships in 1794, one of which, the U.S.S. *Constitution*, is still docked in Boston.

Longer masts as well as jibs (triangular sails set on a stay extending usually from the head of the

foremast) were introduced on European ships during the eighteenth century; all traces of forecastles and aftercastles disappeared; and poop decks were extended to cover the rudder and steering mechanisms, allowing the helmsman to be inside the ship. In 1760 the British introduced copper plating on the bottom planking of their ships to reduce the effects of corrosion and parasites on the hull.

The nineteenth century brought the rise of the large East Indiamen (50 meters long with a beam of 12 meters), which were built in England for cargo rather than speed—the round trip between England and China took about a year. Clipper ships appeared first in the United States in 1820 and were originally intended for the China tea and opium trade but were quickly adapted by British shipyards. One of the fastest British clippers, the *Cutty Sark*, is preserved in dry dock at Greenwich, England. Built in 1869 and famous for its speedy round-trip voyages from England to Shanghai, the *Cutty Sark* is 64 meters long and capable of sailing at 17 knots.

The Eclipse of Sail, 1850–Present

After regular transatlantic steam service began in 1838, only long-distance China trade remained open to sailing ships because steamers could not haul enough coal to make the journey to China and back. In 1869, with the opening of the Suez Canal in Egypt, steamers began to take over the China trade as well, marking the end of the dominance of sailing ships. By the dawn of the twentieth century sailing ships were used almost exclusively as training and pleasure craft, soon symbolizing luxury rather than efficiency.

Saladin

(1137/38–1193)

MUSLIM RULER

Saladin, who ruled over Egypt, Syria, and Palestine in the late twelfth century, was revered in the Muslim Middle East for his military prowess, bravery, piety, largesse, and integrity, and he was romanticized for the same qualities in medieval literature of the Western. He remains today for Arabs a historical figure of near-mythic proportion.

Al-Malik al-Nasir Yusuf ibn Ayyub Salah al-Din (“righteousness of the faith”), or Saladin, was responsible for the near-total destruction of the Crusader Kingdom of Jerusalem; he founded the short-lived Ayyubid dynasty of Egypt and Syria, northern Iraq, and Yemen. He was widely regarded as the epitome of noble, pious, and martial virtues.

Yusuf ibn Ayyub was born in Tikrit (in present-day Iraq) to a Kurdish family in the service of the Seljuk sultanate that at that time ruled much of the region. His father entered the service of the ruler of northern Syria, ‘Imad al-Din Zangi, and was rewarded with the lordship of Baalbek in Lebanon. In the aftermath of European Christians’ failed Second Crusade (1145–1147), Zangi’s heir Nur al-Din took Damascus, fulfilling his father’s ambition to unite the three great Syrian provinces of Aleppo, Mosul, and Damascus. In the 1160s Saladin accompanied an uncle on a series of missions against Fatimid Egypt, which was regarded as a key territory for the containment of the Crusader Kingdom and which Zangi feared was becoming a Frankish protectorate. Yusuf distinguished himself in these campaigns, and on the death of his uncle in the course of the last of these missions, he managed to take control of the Syrian forces and have himself appointed as vizier to the

Fatimid caliph. Taking the honorific title al-Malik al-Nasir (“the king victorious by God”), he became de facto ruler of Egypt. Having consolidated his position in a series of military campaigns, he dissolved the Fatimid caliphate in 1171.

Saladin, King of Egypt, from a fourteenth-century manuscript in the British Library.

European merchants supply the best weaponry, contributing to their own defeat. • Saladin (c. 1137–1193)

After the Third Crusade, a new treaty granted Christian pilgrims access to Jerusalem. Here Saladin meets the Bishop of Salisbury.

These successes troubled Nur al-Din, who planned to reassert his authority over Yusuf, but died in 1174, before a mission could be launched. Over the course of the following twelve years, in a series of military and diplomatic campaigns, Saladin managed to gain control over Damascus and Aleppo and forced Mosul to submit to his authority. Thus secure and with sufficient manpower to draw on, he was able to launch a decisive campaign against the Kingdom of Jerusalem, which was suffering a period of divisiveness and disarray. After smashing the Crusader forces in a single battle at the Horns of Hattin (near Lake Tiberias) on 4 July 1187, Saladin was able to sweep the Franks from Palestine and western Syria, although his failure to take Tyre (on the coast of southern Lebanon) provided the protagonists of the Third Crusade (1189), Richard I of England and Philip II Augustus of France, with an embarkation point. The Franks captured Acre (on the coast of present-day northern Israel, about 60 kilometers south of Tyre) after a bitter two-year siege, and a new treaty granted Christian

pilgrims access to Jerusalem. Saladin died six months later in March 1193.

Saladin's success in uniting the Syrian military classes was due to a number of factors, not the least the force of his own personality: he famously exhibited Arab and Islamic virtues of military prowess, bravery, piety, largesse, and integrity. His skillful use of diplomacy with Franks, Byzantines, and Muslims allowed him to focus his energies, and his ideological program of jihad helped to galvanize popular political support in Syria and beyond. He was fortunate to be assisted by capable and trustworthy subordinates, including his prime minister and ideologue al-Qadi al-Fadil and his brother al-'Adil, who acted as governor of Egypt and who carried out the famous negotiations with Richard I. Saladin preferred to give positions of political responsibility to family members.

The same personal virtues that made Saladin attractive to the Muslim world prompted his adoption by medieval romance writers as a leading character and a paragon of infidel virtue, a paradox that literary

license rationalized variably as the result of a Christian mother, secret conversion, or other factors. In the Muslim world contemporary biographers, such as Baha' al-Din, painted a more realistic but also undoubtedly idealized portrait of Saladin as a pious yet pragmatic king and an advocate of holy war, an image that continues to resonate in the popular consciousness.

The Ayyubid dynasty that Saladin established was essentially a constellation of independent principalities governed by his kinsmen and their descendents. The most important principality was Egypt, which was ruled in turn by al-'Adil and his son al-Kamil, and which survived the thirteenth-century crusades before being supplanted by the Mamluks in 1250. The longest surviving branch of the dynasty ruled Aleppo until that city's capture by the Mongols in 1261.

Salinization

Salinization, the process by which salts accumulate in soil, has long been (and continues to be) one of the world's major challenges for sustaining agricultural production. In natural and managed ecosystems, salinization regulates plant and animal communities, and it determines the way in which water is circulated and distributed on and below the Earth's surface and in the atmosphere.

Salinization is a natural and human-induced process by which soluble salts accumulate in soil. Salts enter soil systems mainly when they are dissolved in groundwater or irrigation water, when they are deposited from the atmosphere, and when minerals are weathered. Salts are further concentrated as water is removed from the soil via evaporation and transpiration (the uptake of water by plants). Slow-draining clayey soils are much more susceptible to salinization than are rapid-draining sands. Salt concentrations in soils tend to increase in the direction of surface or groundwater flow, that is, from uplands to low-lying depressions or bottoms. Salinization thus affects many of the Earth's major biogeochemical cycles of chemical elements and compounds between the living and nonliving parts of the biosphere.

The predominant soil salts are chlorides and sulfates salts, which are generally balanced by sodium, calcium, magnesium, and potassium. Soils with elevated salts are known as "saline," and those with sodium-dominating salt composition are known as "sodic" or "natric." Sodium salts are particularly problematic in soils for physical, chemical, and biological reasons. Excess sodium can stress many plants, especially if calcium concentrations are low, is associated

with very high pH (above 9) and causes conditions directly injurious to plants by worsening deficiencies in nutrients such as phosphorus, copper, iron, boron, manganese, and zinc.

High sodium also adversely affects soil's physical and chemical properties, causing soil clays and organic matter to disperse into individual particles instead of remaining flocculated (i.e., attracted together in packages or aggregates of multiple particles of clay and soil organic matter). Sodium-enriched soils that are dispersed can be a near-complete barrier to water entry as dispersed clay particles block soil pores. Sodium-caused dispersion also reduces the rate of gas movement in soils. Soils that are sodium enriched readily become waterlogged and stress oxygen-demanding processes such as root and microbial activity. Only well adapted salt-tolerant plants and microbes are able to grow in salinized soils.

Plants range widely in their ability to tolerate salts in their root zone. Plants that readily accumulate or tolerate salts are called "halophytes" and include salt-tolerant grasses, herbs, and shrubs, species that are native to deserts, shorelines, and salt marshes. Most food crops are not halophytic and exhibit high sensitivity to salt, including many legumes, corn, rice, oats, and wheat. Crop plants that tolerate or benefit from halophytic properties include beets, date palms, spinach, jojoba, and barley.

Geographical Distribution of Salt-Affected Soil

Salinization occurs chiefly in arid, semiarid, and sub-humid regions. Salt-affected soils are not a widespread problem in humid regions because precipitation is

Table 1.
Distribution of Saline and Sodic Soils on Five Continents

	Saline Soils	Sodic Soils	Ratio of Sodic/Saline
	(in thousands of km ²)		
Africa	535	270	0.5
Asia	1,949	1,219	0.6
Australia	386	1,997	5.2
North America	82	96	1.2
South America	694	596	0.9

sufficient to dissolve and leach excess salts out of the soil into groundwater and eventually the ocean. Some saline soils occur along humid seacoasts where seawater inundates the soil.

The importance of salinization can be illustrated by the large areas soils that are enriched in salts throughout the world. (See table 1.) Fully one-quarter to one-third of the world's 1.5 billion hectares currently under cultivation are saline or sodic, a statistic that demonstrates the impact of salinization on world food production. Salinity is most problematic in cultivated soils that are irrigated. Irrigated lands with large areas of saline and sodic soils include Australia, India, Pakistan, Russia, China, the United States, the Middle East, and Europe. In some nations, salts seriously affect more than 50 percent of irrigated lands. Salinization will be a major problem for successfully doubling to tripling food production in the coming decades.

Reclamation of Saline and Sodic Soils

Salinization is an insidious problem, and early soil symptoms are often ignored. To control salinization and maintain irrigation-based agriculture over the long term requires soil analysis and careful monitoring of water and salt budgets (amounts) of local fields to river-basin scales. Such monitoring provides the technical basis for remedial action.

To diagnose soil salinity problems, soil samples are rinsed with water, and the water's electrical

conductivity is measured. The soil water's conductance is linearly related to the concentration of soluble salts. The conductance at which the growth of many plant species is diminished by salts is well established. Sodium problems are also diagnosed from the ratio of the soil sodium to calcium.

Leaching with high-quality (dilute) water can potentially rid a soil of its salinity problems, but the reclamation of sodic soils is not straightforward. Because elevated sodium tends to disperse soil clays and greatly reduce the rate at which water moves through soil, the ratio of soil sodium to calcium needs to be decreased if sodium leaching is to be effective. Calcium, especially in the form of gypsum, tends to aggregate or flocculate clays, allowing sodium to be dissolved and to leach through the soil-rooting zone. Reclamation of sodic soils may, however, require large amounts of gypsum, sometimes several thousand kilograms per hectare. Gypsum additions can be costly, especially if the only sources of irrigation water have high sodium and salinity.

Reclamation of salt-affected soils requires a suitable system of disposal. In many cases the drainage is too brackish (salty) to be directly recycled. Moreover, in contemporary agricultural systems, drainage effluents also contain other constituents such as fertilizer nutrients, sediments, and pesticides, all of which may influence disposal. Nonetheless, irrigation effluents are often simply exported to streams or rivers, a practice that salinizes and pollutes the local water supplies. Receiving streams will become progressively saltier, and lower reaches may become unfit as a water supply for humans, animals, or crops. Adverse effects on aquifers and estuaries are direct and potentially serious. Improving the efficiency of water and salt budgets of irrigated lands is one of the highest priorities for contemporary agronomy (the branch of agriculture dealing with field-crop production and soil management).

Salinization Historically

Salinization affected the first great agricultural societies such as the Sumerian and Akkadian cultures,

Salt-affected soils on rangeland in Colorado. Salts dissolved from the soil accumulate on the ground and at the base of the fence post. National Resources Conservation Service (NRCS).

societies that developed on the alluvial soils of the Tigris and Euphrates Rivers. The region was initially developed into extensive agricultural fields with irrigated grain, forage, and palm production in the southern reaches of these rivers. Complex canal systems served both for transportation and irrigation, cities were built, and civilization flourished. Over time the irrigated lands shifted significantly northward along these rivers, a pattern frequently explained by a salinity-affected decline in agriculture in the south. Archeological records of the Sumerian civilization suggest that grain production also shifted over the centuries from the -preferred but salt-sensitive wheat to salt-tolerant barley.

The history of salinization in ancient Egypt contrasts greatly with that in Mesopotamia. Salt budgets and timing of annual floods along the Egyptian terraces of the Nile are much more conducive to long-term management than terrace soils of the Tigris and Euphrates. Alluvial soils along the Nile are relatively narrow and well drained, except in the Nile's delta. The Nile's river channel tends to be deeply incised along much of its course, ensuring that the rise and fall of the river affects relatively large fluctuations of the groundwater under river terraces. The Nile's agricultural resources are generally considered to be nearly ideal, given the particular combination of high-quality water, relatively predictable flooding, soil fertility, nutrients, and organic matter. Salinization

has not developed into an acute problem along the Nile, and irrigation-based cropping has continued for about five millennia.

Salinization has stressed other agricultural civilizations in the past. One of the largest of these developed in the Indus River valley of Asia, approximately coincident in time with ancient Sumeria. The area of Indus irrigation systems apparently exceeded those in ancient Egypt and Sumer. Relatively few records exist for these Indus civilizations, although several excavations partly tell their tale (at Harappa, for example). Although archeologists suggest that catastrophic floods, earthquakes, and soil erosion wore down these ancient civilizations, salinization was also probably a major problem. In the twentieth century, salinization greatly stresses irrigation-based agriculture which has spread across nearly 15 million hectares of the Indus River valley.

Historical patterns of salinization in Australia's enormous Murray-Darling River basin are also instructive, given the ample documentation of the effects of land-use history on contemporary soils and agroecosystems. Although the basin covers about 15 percent of Australia's total area, it provides far more than this percentage of the nation's agricultural production, much of which is supported by irrigation. Since European settlement began in earnest by the mid-nineteenth century, extensive areas of deeply rooted *Eucalyptus* forests have been cut over and converted

to relatively shallow-rooted annual crop systems, an ecosystem transformation that has reduced plant transpiration (the use of water by plants) and allowed a larger fraction of annual precipitation to percolate through soil and elevate local groundwater systems. Because the underlying groundwater is saline, substantial quantities of soluble salt have been mobilized into the upper soil and root zone. Evapotranspiration (loss of water from the soil both by evaporation and transpiration from plants) concentrates salts, and about 500,000 hectares of the Murray-Darling River basin are estimated to have saline groundwater within 2 meters of the soil surface. Australians refer to these circumstances as “secondary” salinization (i.e., human affected), reserving the term *natural salinization* to describe naturally occurring saline soils that occur in association with salt lakes in drier regions of the continent or adjacent to estuaries.

Salinization in the Future

Irrigated land today totals approximately 0.3 billion hectares of the 1.5 billion hectares of total cultivated land. About 35 percent of total crop output is currently derived from irrigated systems, a percentage that is expected to increase. Between the 1960s and the late 1990s irrigated land increased at the rate of about 3 percent per year. Five nations account for about two-thirds of the irrigated area: China, India, Pakistan, Russia, and the United States. Other nations dependent on irrigated systems include Egypt, Indonesia, Iraq, Jordan, and Israel. All indications are that in the future, irrigation management of water and salts will be increasingly important because global agricultural production is so dependent upon irrigation. The challenge, however, is that contemporary management of irrigated systems is far less than optimal and in fact presents serious concerns for the future. Several examples illustrate the challenges.

The extensive modern irrigation system along the Indus River, mainly in Pakistan, is one of the major agricultural regions of the modern world. Alluvium and associated native groundwater reservoirs are deep in this great basin, which drains the western

Himalayas. Nearly 15 million hectares were under irrigation by the mid 1990s, with the length of irrigation watercourses, farm channels, and field ditches estimated to exceed 1.5 million kilometers. Early in the development of this massive system, saline groundwater tables were observed in the rooting zone of many fields, and by the 1960s a massive drainage project was launched that by the 1990s had benefited about one-third of the entire system. Currently, between 2 and 5 million hectares of irrigated fields are adversely affected by salts. Keeping this system operational will require an incredible continuity of effort, especially because the Indus drainage channels have such low elevation gradients (e.g., about a 0.02 percent gradient), which must transport water many hundreds of kilometers to the ocean outlet.

In modern Egypt the challenges of controlling salinization in irrigated agro-ecosystems have become similarly serious. From ancient times to the beginning of the nineteenth century, the human population of the Nile River valley totaled several million people, most of whom were supported by the river's irrigation-based agriculture. Through most of this past, Egypt was able to export enormous amounts of food, a situation that is no longer the case. Modern Egypt has now about 60 million inhabitants, a total that is expected to grow to 90 to 100 million by 2030. Along with rising agricultural imports, Egypt is placing enormous demands on its irrigated soils for domestic food production. The Aswan High Dam, constructed in the 1960s, established management control over the Nile's flood flows and thereby expanded opportunities for irrigation. On the other hand, with river flow controlled, the seasonality of river flow no longer regularly and flushes soils of salts. Particularly in the alluvial soils of the great Nile Delta, salts have grown to be an increasingly common problem. Future expansions of irrigation agriculture along with highly engineered drainage projects to control salts are widely contemplated.

Future problems with salinization are hardly confined to irrigated lands. Natural cycles of rainfall in arid and semiarid climates can be associated with expansion and contraction of saline and sodic soils.

The saline ecosystems of Amboseli National Park in Kenya at the foot of Mt. Kilimanjaro provide a celebrated and much debated example. From the 1950s on, the vegetation of much of the Park has markedly changed from forested savannahs with *Acacias* to a landscape more dominated by salt-tolerant grasses and shrubs with only occasional trees. A long-standing hypothesis for the ecosystem transformation has been that when regional rainfall increased through the 1960s, highly saline groundwaters rose into the root zone of *Acacia*-dominated savannas, causing widespread tree decline. Whether or not the transformation of the Amboseli is explained by salinization, the Amboseli serves as an outstanding example of how future climate change in the decades and centuries ahead may affect salt balances and salinization across wide areas and thereby the structure and function of natural ecosystems.

Salt

Salt is an essential nutrient but harmful when consumed to excess. The abundance or lack of salt in various locations made it a valuable, traded commodity throughout history. After 1800, salt became a part of manufacturing—for alkali, aniline dyes, and rayon, for instance—and more recently for melting snow and ice. More than half of the total amount of salt produced annually is now destined for industrial use.

Salt (chemical compound NaCl) is essential for human life. The cells of our bodies exist in a bath of salty fluids, and since we excrete salt by sweating, urinating, and spitting it is necessary to take in appropriate amounts of salt to maintain a steady concentration in our bloodstreams. Since other animals share our salty bodies, a diet rich in meat supplies enough salt to replace losses, but diets that consist almost wholly of grain and other vegetable foods lack enough salt to maintain the salt balance. Resulting shortage manifests itself in a persistent craving for mineral salt, wherever it can be found.

But salt is also an addiction. People who get used to adding salt to their food soon find unsalted food flat and tasteless. This is not usually harmful since kidneys excrete excessive salt into the urine, but a lifetime of eating lots of salt can sometimes bring on dangerously high blood pressure. In practice, consuming some salt is a necessity for vegetable eaters but most of the table salt people use today and have consumed for centuries is over and above what our bodies actually require.

Salt in Early History

As long as humans lived as hunters and gatherers, the meat in their diet meant that salt intake was adequate to their bodily needs. But when settled farming villages arose in different parts of the world, beginning about 11,000 years ago, much enlarged human populations soon killed off most wild game animals within reach, so communities came to depend mainly on vegetable foods and had to find ways to supplement them with small but essential quantities of mineral salt.

Fortunately, salt is common. The oceans constitute the Earth's most obvious salt reservoir; but salt lakes, salty earth and salt springs exist in desert and some other inland locations. But from the point of view of farmers, geography played a nasty trick on them, since where rain fell regularly and crops grew best, salt was thoroughly leached from surface soils, and carried off to the sea in streams. So in well-watered landscapes local salt supplies were hard or impossible to find.

Just how local populations coped with this problem in Neolithic times is completely unknown, and written records surviving from early civilizations have nothing to say about salt either. But we do know that durable precious objects like gems, shells, flint and obsidian traveled across hundreds of miles in Neolithic times and when the domestication of donkeys permitted caravan trade to get organized, beginning perhaps about 5000 BCE, the radius and regularity of overland trade exchanges increased. So there is every reason to believe that salt and other consumables, like mood-altering drugs, were also

Eugène-Alexis Girardet (1853–1907), *Salt Caravans in the Desert* (n.d.). Oil on canvas.

exchanged across long distances from the time farming populations first began to feel the craving for supplies of mineral salt.

In Southwest Asia, where wheat and barley farming originated, the closest and richest source of mineral salt was the Dead Sea shore, and it is probably not an accident that Jericho, situated on the Jordan River, and controlling the best route to the Dead Sea, is the earliest fortified site archaeologists have discovered. Dues in kind collected from travelers passing through on their way to gather salt from the shore of the Dead Sea may well have enriched Jericho's rulers and done much to sustain the stronghold they built about 8000 BCE.

Nothing comparably suggestive about long-distance salt trade is known about other early centers of agriculture. But millet farmers in China and Africa, root and rice farmers in Southeast Asia, corn, squash and bean farmers in Mexico, potato and quinoa farmers in Peru all needed mineral salt to supplement their diets as much or more than the wheat and barley farmers of Southwest Asia did. That is because the Southwest Asian cereal farmers acquired a more diversified array of domesticated animals than others, and so had more meat as well as better transport at their disposal.

When what we call civilization brought states and cities and radical differentiation among occupational specialists into being, beginning about 3500 BCE, the salt trade surely grew, if only because larger human

populations continued to depend on the crops village farmers produced. But for a long time there is little or no written or archaeological evidence of salt transport and trade that anyone can point to.

Yet we can surmise that where concentrations of mineral salt were not available on land surfaces, people soon learned how to tap the vast stores of salt dissolved in seas and oceans. That required artificial arrangements to construct shallow ponds of seawater, and then allow the sun's heat to evaporate the water until the salt became too concentrated to remain dissolved. It was not hard to discover this technique, since salt is deposited naturally on the seashore wherever natural pools evaporate in summer time. Artificial pond building and tending was therefore probably invented many times over along suitably warm and dry coastlines. Mediterranean and Indian Ocean coasts were especially well suited to salt production, and we can assume that as the technique became familiar, adequate sources of salt for needy farmers were in fact created by deliberate action. After all, it only needed patience to produce mineral salt dependably once picks and shovels had shaped a suitably shallow pond and closed off its inlet.

Salt as a Trading Commodity

Around the shores of the Mediterranean, the practice of evaporating sea salt probably established itself with

the spread of agriculture itself. Later, when farming also established itself further north in Europe, where climate was wetter and evaporation slower, it was too cool and it rained too much to allow reliable salt production through evaporation. Instead, first peddlers then ships began to carry Mediterranean salt to the northlands. Records of the salt trade begin to appear in medieval times. By then northerners depended for most of their salt on imports from Mediterranean salt pans.

We know far less about salt production along the coasts of the Indian and Pacific oceans. Still it is very likely that the practice of sea water evaporation spread very widely there within climatic limits, and supplied inland farmers with the salt they needed either through peddling, or by moving it cross-country through systems of reciprocal gift-giving among neighboring farmers. In the Americas an organized salt trade existed among Mayans and Aztecs and salt was also used in religious rituals. But nothing is known of how ordinary farmers got salt. Both Mexico and Peru had dry areas where salt existed on the surface for the taking and evaporating seawater was perhaps unnecessary. In Africa, too, inland salt abounded, and Roman records show that distributing salt mined from surface deposits in the Sahara desert became an important source of wealth for West African rulers when camel caravans began to carry it both north and south of the Sahara after about 300 CE.

In general, then, early farmers were able to get hold of the small amounts of mineral salt they needed to maintain the necessary saltiness of their bodily fluids. The salt they consumed came from multiple, sometimes local, sometimes distant sources, and left next to no trace in archaeological or written records. Distributing the small quantities of salt everyone needed required no special effort or organization; and large-scale transport of salt by ship or caravan remained exceptional.

This began to change in China under the Han dynasty when Emperor Wudi, in 119 CE, sought to repair his imperial finances by monopolizing salt and iron, in order to sell these essential commodities to his subjects at artificially high prices. This appears to be the first time a powerful government embraced

the idea of taxing salt, and it was not in fact very successful, since the Chinese bureaucracy was not actually able to control salt distribution from the multiple sources along the coast and inlands well. Yet the idea of taxing salt was too enticing to give up since it was something everyone needed and, if government officials could successfully monopolize supplies, both rich and poor were ready to pay a lot for it.

When the technology of salt production in China shifted toward underground mining, effectual monopolization became more nearly practicable. A critical breakthrough occurred under the Tang dynasty when, about 780 CE, new taxes on salt were dedicated to maintaining the canal and transport system that linked the Yangzi (Chang) with the Huang (Yellow) River, thus supplying the imperial capital with food and other resources from the south in far greater quantity than before.

Increasingly efficient and productive underground mining of salt in the inland province of Szechwan was what made it possible to tax salt so heavily as to make it a major source of imperial finance. Techniques were complex and expensive to install. Consequently producing salt from underground became easy to monopolize. What happened was this: Chinese engineers learnt how to exploit underground salt beds in Szechwan by drilling wells, pouring water into them to dissolve the salt and then pumping saturated brine back to the surface. They then passed the brine through a succession of evaporation vats, precipitating mineral salt of varying qualities quicker and in larger quantities than sea water (with only about 3 percent of its weight consisting of salt) could possibly supply. The salt administration under the Tang and later dynasties became extraordinarily sophisticated, controlling the manufacture, distribution, and sale of salt throughout China, and lowering prices in regions close to the coast so as to compete with illegally manufactured sea salt, which the government was never able to eliminate completely.

Salt manufacture and distribution thus became a major source of tax income for the Chinese government and helped to sustain China's political cohesion across subsequent centuries. The scale and technical efficiency of salt mining in Szechwan was unmatched

elsewhere. Indeed it should be recognized as the largest industrial complex on Earth before steam engines permitted the rise of Manchester and Birmingham in England after 1780.

Indian and European governments imitated the Chinese in trying to tax salt, but wherever numerous, small-scale salt evaporation sites existed along the seacoast, government monopolies were hard to enforce, and salt taxes remained both unpopular and marginal. But in central Europe, in and around Salzburg, Austria, underground salt beds existed near the surface, and the Hapsburg monarchy (1273–1918) grew great very largely on the strength of income from taxes on salt, produced, as in China, from underground. The French monarchy tried to do likewise, but since the French coastline abounded in privately managed salt pans, efforts to impose monopoly prices met with indifferent success since even in inland provinces, where the salt tax was most vigorously enforced, smuggling untaxed salt could not be prevented. Everywhere the salt tax remained unpopular, and when the French revolution broke out in 1789 the National Assembly abolished the tax.

Further east, near Cracow in Poland, beds of unusually pure underground salt also existed, and the soil on top of it was so dry that salt could be mined by using picks and shovels, leaving extensive underground caverns behind. Today these caverns run for miles a few yards beneath the surface. Salt merchants from Venice discovered (or perhaps enlarged and reorganized) these mines in the fourteenth century. The salt trade had been important for Venetians from the time of the city's foundation in the sixth century, since the climate along the adjacent coast of the Adriatic was especially dry and well suited to the Mediterranean style of salt-making by evaporation. Venetians (in competition with other Mediterranean seafarers) had supplied salt to northern Europe for centuries; and the expansion of salt production in Poland did not disrupt Mediterranean salt-making and export to the north.

All the same it is likely, though not sure, that Polish salt mines lowered prices and increased the quantity of salt available along the Baltic coast and in Holland.

Only careful study of salt prices could tell for sure what happened; but there is reason to believe that more and cheaper salt began to flow across the Baltic in the fourteenth century since that was when European fishermen began to sail further and further into the Atlantic, preserving their catch by covering the fish with salt and storing them in barrels for days or weeks until they returned home and took their catch ashore. Very likely the Polish government, unlike their Hapsburg neighbor, was too weak to monopolize mined salt, so market prices prevailed. If so, that meant lower prices, since mining Polish salt was comparatively simple, quantities were easy to increase, and shipping down the Vistula was inexpensive. All we know for sure is that after about the mid-fourteenth century, salt, cheap enough for fishermen to buy and use in large quantities, became available along the Baltic, North Sea, and Atlantic coasts as never before. Some came from Poland, some from old-fashioned Mediterranean salt pans, which could expand production almost as easily as the Polish miners by building more evaporation ponds. Dutch (and other) ships, carrying salt to and fro, kept market prices low for them both.

Historical Implications

This was important for world history, and goes far to explain why European instead of Japanese seamen discovered America. For, even though fishermen do not usually tell where fishing is best, there is good reason to believe that exploration of the breadth of the Atlantic carried European fishermen to the Grand Banks and the shores of Newfoundland some decades before Columbus made his famous voyage. And it is certain that their voyaging, together with what the Portuguese did to explore the coast of Africa, accumulated knowledge of winds and currents and other skills needed for the trans-oceanic voyaging that European navigators achieved so spectacularly between 1492 and 1522.

Nothing similar happened in the North Pacific where Japanese fishermen had boats just as good as what Europeans had, but lacked large amounts of

Let there be work, bread, water and salt for all. • Nelson Mandela (b. 1918)

cheap salt, so stayed close to shore where they could get their catch to market within a day or two. Once out of water, fish rot quickly, so catching them across an ocean from where they were sold, as Europeans began to do after about 1450, made no sense without cheap and abundant salt to preserve the catch. Japanese fishermen therefore lost the chance of harvesting salmon and other fish in American coastal waters, and, of course, did not discover America either.

One may therefore argue that Europe's expanding salt supply, by permitting deep sea fishing to flourish as never before, tipped world history toward transoceanic navigation and settlement—an achievement that dominated human history for the next five hundred years by profoundly reshaping global demography, economics and politics. If so, this surely counts as the biggest impact salt ever had on human affairs.

After about 1800, official salt monopolies and systems of taxation built upon them weakened or disappeared, not just in revolutionary France, but in other European countries and in Asia as well. In India, for example, British efforts to maintain salt taxes were never very successful and by the 1930s protest against the salt tax became one of Mohandas Gandhi's ways of mobilizing popular opinion against the Raj, when he went to jail for personally making untaxed sea salt. Even in China the salt administration suffered serious disruption when a long series of rebellions broke out, beginning in 1774 and climaxing with the Taiping convulsion of 1850–1964.

Wherever cheaper and more abundant salt became available, whether from breakdown of tax monopolies or through improved methods of production and distribution, it could be used to preserve meat and other foods as well as fish. This added a good deal to human food supplies in many parts of the world. In the Polish and German part of Europe this was particularly evident, beginning as early as the fourteenth century, for, in addition to salted ham and sausages,

sauerkraut, made by salting cabbages, provided a very valuable source of vitamins otherwise seriously lacking from their winter diets.

Eventually, beginning about 1800, all the age-old uses of salt for human consumption and food preservation were eclipsed, at least in scale, when chemists learned how to use salt in various industrial processes. It became an ingredient for manufacturing such diverse items as alkali, aniline dyes, rayon and innumerable other new chemicals. A still more recent use for salt is for melting snow and ice from roads in winter. As a result, more than half of the total amount of salt produced annually at the close of the second millennium—something like 225 million tons—was destined for industrial uses. And, strange to say, taxing cheap and abundant salt no longer attracts much attention from the world's governments.

Sasanian Empire

The Sasanians, or Sasanids (224–641 CE) were responsible for creating an important empire that included the Plateau of Iran, parts of Central Africa, Arabia, and Mesopotamia. Their artistic talent and cultural creativity influenced their neighbors, and their history remained a reference point for the later Islamic dynasties that arose in the same area.

During the height of Sasanian power in the seventh century the empire controlled Anatolia (peninsular Turkey), Syria, Palestine, and Egypt, as well as parts of Iran, Central Africa, Arabia, and Mesopotamia. The Sasanians were an important part of the Silk Roads economy, which controlled the sale of silk and other luxury goods in Eurasia, and they produced the most recognized monetary system, specifically the coinage known as the silver *drahm*.

Rise of Ardashir I

The Sasanians rose up from the province of Persis (present-day Fars, in southwestern Iran), where Persian customs had remained constant and a historical memory of the past prevailed. Ardashir I (reigned 224–240 CE) was the son of a priest who served at the fire temple of the goddess Anahita in the city of Istakhr. Ardashir was able to conquer the province in the first decade of the third century CE while the nominal ruler of the area, the Parthian king of kings Artabanus VI, was busy with the Romans and fighting off contenders to the throne. By the time Artabanus VI was able to pay attention to the Persian upstart, Ardashir had gathered a large force, composed mainly

of the Persian nobility. Ardashir defeated Artabanus VI in 224 and crowned himself king of kings. His coins and inscriptions call him “Ardashir, King of Kings of Iran, who is from the race of gods.” It was the first time that the name “Iran” was used to designate the Plateau of Iran as such.

Shapur I and the Prophet Mani

Ardashir’s son, Shapur I (reigned 240–270 CE), had many military successes. He was able to kill one Roman emperor (Gordian), imprison another (Valerian), and make the third a tributary (Philip the Arab). His armies captured many Roman and Germanic (Gothic) soldiers, who were placed in royal cities as engineers, craftsmen, and laborers. This Roman influence is clearly seen in the city of Bishapur in the province of Persis. Shapur I left several long inscriptions and rock reliefs attesting to his grandeur and power as the king of kings of not only Iran, but also of what he called non-Iran. This means that there was a clear notion of what lands were considered Iran and what parts of the Sasanian Empire comprised lands beyond Iran.

During Shapur’s reign the prophet Mani (c. 216–c. 274 CE) appeared in Mesopotamia. He was from a Parthian noble family that professed a syncretic, Gnostic religion that combined elements of Zoroastrianism, Buddhism, Hinduism, and Christianity. Central to Mani’s religion were the two principles of light and darkness. The realm of light was the spiritual realm, while the realm of darkness was the realm of flesh. The history of the world was divided into three eras: the first era, in which the two principles were separate; the second era, in which the principles were

*Bahram and the Indian Princess in the Black Pavilion, a miniature gouache (16th c.), based on a story about the Sasanid king Bahram V as told in the *Khamse* (quintet of poems) written in the twelfth century by Nezami.*

mixed because the realm of darkness attacked the realm of light and entrapped light particles; and the third era, when the ideal state of separation returned the realm of darkness was ultimately destroyed. This

religion, known as Manichaeism, became quite popular with the traders and businessmen; consequently it spread along the Silk Roads. Shapur I, although a Zoroastrian, allowed Mani to profess his religion freely throughout the empire, which made the Zoroastrian priests resentful. After Shapur's death, the priests contrived to have Mani arrested and then killed. Mani's followers were dispersed and fled to Central Africa and China.

Zoroastrianism in the Sasanian Period

Zoroastrianism, the religion professed by the Sasanians, was the official religion of the empire from the third century. Although other Zoroastrian deities such as Mithra and Anahita were also worshipped, and in fact the Sasanians were the caretakers of Anahita's fire temple, in their inscriptions the Sasanians describe themselves as "Mazda worshipping." That means that Ahura Mazda (Middle Persian *Ohrmazd*) was the supreme deity. The society was stratified according to the Avesta, the Zoroastrian scriptures, and three major fire temples were established: the Adur Farranbag fire temple for priests, the Adur Gushnasp fire temple for warriors, and the Adur Burzenmihir fire temple for farmers and husbandmen. A host of smaller fire temples were also established throughout the empire where the teacher priests uttered the sacred words and formulas and performed the necessary rituals.

There are two priests from the third century mentioned as the architects of the Zoroastrian state religion and the builders of the Zoroastrian hierarchy. The first is Tosar (or Tansar), who is said to have collected all the traditions relating to the Avesta and compiled an authoritative version during the time of Ardashir I. The next pivotal figure in the history of Zoroastrianism was Kerdīr, who surveyed the empire, established the version of Zoroastrian religion which he saw fit, and spread those doctrines. He honored the priests who followed his teachings and punished those who opposed him. Kerdīr mentions

that he persecuted other religious groups within the empire, namely the Christians, Mandeans, Buddhists, Hindus, and Manichaeans. It was he who instigated the arrest and execution of Mani. He also established many fire temples, and his followers believed that he made a journey to the nether world to find out about heaven and hell and how to end up in one and avoid falling into the other. Kerdir lived through the reign of several Sasanian kings and he rose to absolute power in the second half of the third century.

Fourth and Fifth Centuries: War and Revolution

In the early fourth century the wars with the Romans was disastrous for the Persians. King Narses (reigned 293–302 CE) lost several major battles—and his entire harem—to the Romans and was forced to pay a heavy ransom for the harem's release. In religious matters, however, it appears that Narses was able to reduce the power of Kerdir and the priests and give special importance to the goddess Anahita again. Later in the fourth century Shapur II (309–379 CE) avenged the losses of Narses and was able to defeat the Romans. He also was able to defeat the Arab tribes who had attacked and ravaged the southeastern provinces of the empire, which explains his title in the Islamic literature, “piercer of shoulders” (Arabic *dul al-aktaf*).

In the fifth century, during the reign of Yazdegerd I (reigned 339–420 CE), the patriarch of the Nestorian (Christian) Persian Church was established at the Sasanian capital, Ctesiphon. Yazdegerd I also married the daughter of the chief rabbi in the Sasanian Empire, from whom the next king of kings, Bahram IV (reigned 388–399 CE) was born. These actions brought a sense that the empire belonged to citizens of all religions: as long as they paid their taxes, they were part of the empire.

It was also in the fifth century that the Hephthalites attacked from the east. The Sasanians had to fight the Arabs and the Romans on the southwestern and

western front. By the end of the fifth and early in the sixth century, under the rule of Kavadh I (reigned 488–496 CE; 499–531 CE), the society went through a revolution. Using a novel interpretation of the Avesta, the magi (priest) Mazdak helped king Kavadh to reduce the power of the landed nobility, who exerted a lot of influence and were immune from paying taxes. Their lands were redistributed among the people, and new small-landed gentry became the backbone of the state. The power of the clergy, who had supported the earlier status quo, was also reduced.

Khosrow I and His Reforms

Kavadh's son Khosrow I (reigned 531–579 CE) came to the throne after defeating his brother. His first action was to make peace with the Romans and secure the borders of the empire. He then began the capture and persecution of Mazdak and his followers. Once the king had been able to reduce the power of the clergy and the nobility, they again began to bring the empire back to order. Khosrow I, however, did not restore any land to the nobility, but rather made the smaller landowning gentry the backbone of the society and tax infrastructure. Khosrow I surveyed the land and created a new tax system that taxed not only the land but also its produce, to be paid in three installments annually. He also divided the empire into four cantons, one the northeast, one in the southeast, one in the southwest, and one in the northwest. The military was also divided into four sections, one to take charge of the defense of each canton. This was in an attempt to combat the invasions that came from all directions.

Religiously, the Avesta and its commentary (the Zand) were placed under the direction of trusted magis whose interpretation was accepted by the king. The Avesta was written down in its final version, along with its interpretation. The royal chronicle that described the history of Iran, known as the *Khudy-nmag* (Book of Kings) was also written during Khosrow's rule. Khosrow encouraged intellectual inquiry, inviting philosophers from the Byzantine Empire to come

to Persia, where they wrote works on Aristotelian philosophy and other sciences for the Persian king. Khosrow also sent to India for books on astronomy, logic, and wisdom literature. Khosrow's minister, Wuzurgmihr, was renowned for his wisdom even in the post-Sasanian (Islamic) period. Such games as chess and backgammon were also introduced to Iran from India at this time. The game of polo was already a kingly sport and played at the time of Khosrow I. Khosrow's court was also known for its opulence: his crown was so big and heavy that it had to be suspended from the ceiling.

Sixth and Seventh Centuries: Iran

Khosrow II (reigned 590–628 CE), a vigorous ruler, oversaw the conquest of Egypt and the siege of Constantinople, but the Byzantine emperor Heraclius was able to strike back and defeat the Persians. The riches and the opulence of Khosrow II's court and palaces became legendary in the later Islamic period. His love for an Armenian wife of his, Shirin, was recorded in romances and epics, as was the beauty of his horse, Shabdiz. During his rule performers and musicians gained fame, especially the composer-performer Barbad and the female singer Nakisa. The artistic expression of the late Sasanian period is captured in the monuments at Taq-e Bistan and also at Bisitun, where there appears to have been a plan to carve a monumental rock-relief that was never finished.

After Khosrow II, his sons, grandson, and daughters came to the throne. Queen Boran (reigned 630–631 CE) is known to have tried to revive the memory of her father and to bring order to the chaotic empire after his death. Queen Azarmiduxt, the sister of Boran, ruled for a short time as well. Their reigns attest to the fact that women were allowed to rule the Sasanian Empire. A series of distant relatives then competed for the throne, ending with the accession of Yazdegerd III (reigned 632–651 CE), the last Sasanian king. By then the Arab Muslim armies were on the march; they defeated the Sasanians in three major battles. Yazdegerd III attempted to gather forces to

fight the invaders, but he was murdered in Khorasan by a local governor who did not want to support the wandering king. His sons and daughters fled to China seeking help. Even his grandson in the eighth century was hoping for the recapture of Iran, but by then the world of Iran had changed and a new dominant force, the Marwanids, were in power.

Sasanian Legacy in World History

Many Sasanian customs were passed on to the Islamic world, including games such as polo, chess, and backgammon. Wisdom texts from India and Iran and manuals on how to rule and manners of conduct were translated from Middle Persian into Arabic. Iranian administrative practices became the dominant feature of the Islamic administrative system, and the Sasanian silver coinage became the model of Islamic coinage. In the ninth century, with the breakup of the Islamic Abbasid power, claims to Sasanian heritage became a main component of the ideologies of the local dynasties that vied for power on the Plateau of Iran. This fact suggests the enduring power and importance of the Sasanians in the memory of the people of Iran and neighboring lands.

Science—Overview

Like all effective knowledge systems, science is based on induction: careful empirical observation followed by attempts to generalize. Like all knowledge systems, it is subject to falsification, to the sudden appearance of new realities, or to new forms of information that may overturn established certainties. What distinguishes modern science from earlier knowledge systems is the size of the intellectual arena within which its ideas are generated and tested.

The English word *science* derives from the Latin *scire*, “to know.” In many languages, the word *science* or its equivalents can be used broadly to mean “a systematic body of knowledge that guides our relations with the world.” This is the sense that is present in phrases such as “the social sciences.” There have existed many different knowledge systems of this type. All animals with brains have, and make use of, structured knowledge of the external world, so in principle we could claim that even animals depend on some form of science.

Used in a narrower sense, the word *science* refers to the distinctive body of systematic knowledge about the material world that emerged in Europe within the last five hundred years and that underpinned the technological achievements of modern societies. Many societies have had complex technologies, and many have had rich and rigorous systems of religious and philosophical thought, but what is distinctive about modern science is that its theories have been used to generate extraordinarily powerful and effective technologies. As a recent study puts it, “Modern science is not just a thought-construction among others—it entails both an intellectual and an operative mastery

of nature. Whereas empirical technology is a feature of every major civilization, the systematic application of scientific insights to change our natural environment (‘to conquer Nature by obeying her’, as Francis Bacon phrased it) is a creation of Europe alone” (Cohen 1994, 4). Conceived in this sense, science is a distinctively modern way of understanding the world. So, to understand the modern world, we have to understand science.

The idea of a “scientific revolution”—a fundamental transformation in ways of thinking about the world—is central to this view of the role of science in world history. Though it is generally accepted that the roots of modern science can be traced to classical Greece and Mesopotamia (although anticipations of modern scientific thought can be found in many different societies, from China to Mesoamerica, and even in some aspects of Paleolithic thought), it is widely assumed that modern science appeared during the scientific revolution of the sixteenth and seventeenth centuries, and its appearance marked a fundamental intellectual shift. As one survey puts it, “The Scientific Revolution represents a turning point in world history. By 1700 European scientists had overthrown the science and worldviews of Aristotle and Ptolemy. Europeans in 1700—and everyone else not long afterwards—lived in a vastly different intellectual world than that experienced by their predecessors in, say, 1500” (McClellan and Dorn 1999, 203). Over the next few centuries that revolution transformed human attitudes and human relations with the material world.

But the notion of science as a revolutionary new form of knowledge raises some complex problems. Was modern science really that different from earlier

A page from a noteworthy treatise on optics, written under the Ottoman sultan Murat II (reigned 1512–1520), begins with the basics (direct vision, reflection and refraction, and the length of shadows).

systems of knowledge? Why has it given modern societies such astonishing leverage over the material world? And is it really true, as some have claimed, that modern science offers a fundamentally superior way of describing reality?

What Is Different about Modern Science?

Answering these questions is not easy. It has proved particularly difficult to show that science offers a more accurate description of the world than earlier systems of knowledge.

Some of the earliest attempts to explain the efficacy of modern science claimed that its defining feature was careful, objective observation of the material world. Whereas most earlier systems of thought relied heavily on religious revelation or on the traditional

authority of earlier writers and thinkers, so these claims go, scientists tried to put aside all preconceived notions and observe the world directly and without bias. To ensure the objectivity and precision of their observations, they devised rigorous and sometimes complex experimental methods. Then, using the results of their observations, they came up with general hypotheses about the nature of reality, using the logical method of induction.

In this view, scientific theories work because they are based on meticulous observation and rigorous logic, which explains why they offer exceptionally accurate and useful descriptions of the world. Galileo Galilei (1564–1642) is often thought to have exemplified the new experimental methods in his observations of the sun and planets through the recently invented telescope and in his experiments rolling balls down sloping planes to study the effects of gravity, while the achievement of Isaac Newton (1642–1727) in formulating general laws of motion is often taken as a paradigm example of the possibilities for radical generalization on the basis of information derived from careful observation. The seventeenth-century English natural philosopher (the contemporary term; now we would say *scientist*) Francis Bacon (1561–1626) was probably the first to describe the method of induction systematically, but similar arguments about the nature of modern science are still widely held today. Here, for example, is a modern definition of how science works: “Scientists propose theories and assess those theories in the light of observational and experimental evidence; what distinguishes science is the careful and systematic way in which its claims are based on evidence” (Worrall 1998, 573).

There is much truth in the inductivist view of modern science. Though examples of careful, empirical observation can be found in all human societies, never before had so many scientific observations been conducted so systematically and with such care and precision, and never before had natural philosophers tried so rigorously to build from them universal theories about the nature of reality. Unfortunately, though, the method of induction cannot guarantee the truth

In questions of science, the authority of a thousand is not worth that humble reasoning of a single individual. • **Galileo Galilei (1564–1642)**

of scientific theories. In the first place, it is now clear that our minds shape and reorganize information as they receive it; so we can never separate observation from theorization in the neat way presupposed in the simplest models of inductive logic.

But the most fundamental problem is logical. Induction leads us from particular observations about the world to general theories about the world. Yet no observations can embrace all of reality, so induction involves a leap of faith that the small sample of reality that we can observe directly is characteristic of the whole of reality. Though it makes sense to rely on theories based on a large body of empirical evidence, induction can never yield conclusions whose truth is certain. (Bertrand Russell's famous example was the inductivist turkey, who observed carefully how, each day, her bipedal servants provided food at a particular time; unfortunately, in mid-December, just as the turkey was about to formulate the general hypothesis that food would always appear at the same time, her servants killed her and cooked her for Christmas.) As a result, conclusions based on induction are always subject to modifications, sometimes of the most fundamental kind, as new observations become available. Thus, by carefully observing the position and motion of distant galaxies, using work on variable stars by Henrietta Leavitt (1868–1921), Edwin Hubble (1889–1953) showed that the universe, far from being stable and eternal, is in fact expanding.

Early in the twentieth century, the British-Austrian philosopher Karl Popper (1902–1994) proposed what he hoped was a more reliable apology for science. He argued that science advances through a process of “falsification.” As he pointed out, even if it is impossible to prove the truth of any theory reached by induction, it *is* possible to prove that some theories are wrong. So Popper argued that science should be trusted not because its conclusions are true in any absolute sense, but because it consisted of theories that had been tested rigorously and had not yet been proved wrong. The best known example of a falsifiable idea is perhaps the claim put forward by Albert Einstein (1879–1955) that gravity affected light, a claim he suggested could be tested by seeing if the

light from distant stars was bent as it passed behind the sun. The claim was successfully tested in 1919 during a solar eclipse, but what interested Popper was that Einstein's claim was risky: it could have been proved false. Popper argued that ideologies such as Marxism and disciplines such as history did not count as sciences because they did not generate hypotheses that were precise enough to be falsified. Marxism was simply too rubbery: when it was pointed out that the socialist revolution predicted by Marx had failed to materialize, Marxists simply shifted their ground and changed the anticipated date of the revolution.

Unfortunately, even Popper's attempts to distinguish science from other forms of knowledge were shown to be inadequate as historians of science became aware of the extent to which scientists, too, could cling to outdated theories or tweak their theories to avoid falsification. Despairing of finding any decisive proof of the truth of scientific theories, some philosophers of science gave up. The historian Thomas Kuhn (1922–1996), impressed by the subjectivity and partisanship of real science, argued that the main defining feature of modern science was simply that scientists within each scientific discipline seemed to agree about the discipline's core ideas. Sciences, he argued, were organized around paradigms, or core ideas, such as Newton's laws of motion, or the theory of natural selection. Once firmly established these were rarely subjected to the rigorous testing procedures Popper had taken for granted; on the contrary, there was a powerful element of faith in the work of most scientists most of the time. Paradoxically, Kuhn argued that it was this faith in a core idea that explained the effectiveness of scientific research. Unlike historians, who cannot agree about the fundamental laws by which their discipline works, scientists commit to a certain body of theory and this, he argued, explains why they conduct research in a more coordinated and more effective way than historians. For example, biologists, working within the paradigm of natural selection, know that any observation appearing to threaten the fundamental principle of natural selection is important, so such problems attract many researchers, and eventually

their work can lead to new insights that usually support the core paradigm.

But not always. In extreme cases, he conceded, the accumulation of new data and new ideas may lead to the overthrow of an existing paradigm. In the late nineteenth century, most physicists assumed the existence of “ether,” a universal medium within which all physical processes took place. Unfortunately, experiments on the speed of light by the U.S. researchers Albert Michelson (1852–1931) and Edward Morley (1838–1923), seemed to show that the ether did not exist—the speed of light was uniform in all directions, whereas the existence of an ether ought to have slowed light beams traveling against the ether’s flow. It was these anomalies that led Einstein to suggest that the Newtonian paradigm had to be revised. So Kuhn distinguished between normal science, the slow, sometimes plodding process by which scientists flesh out the implications of a well-established paradigm, and scientific revolutions, or periods when an established paradigm breaks down and is replaced with a new one.

Though Kuhn’s ideas may have offered a more realistic portrayal of how science actually works, they provided weak support for its truth claims and failed to account for its explanatory power, for it was easy to point to other knowledge systems, including most forms of religion, in which there existed a core body of ideas that were taken on trust but were sometimes violently overthrown. To some, it began to seem that all we could say about science was that it was better at solving the sorts of problems that need to be solved in modern societies. Instrumentalist theories of science argue that it does not really matter whether or not scientific theories are true—all that matters is whether they work. Science is best thought of not as a more or less accurate description of reality, but rather as a tool—the mental equivalent of a stone axe or a computer. Or, to adopt a more precise analogy, it is like a map of reality. As Michael Polanyi has written: “all theory may be regarded as a kind of map extended over space and time.” Similarly, Thomas Kuhn has argued that scientific theory “provides a map whose details are elucidated by mature scientific

research. And since nature is too complex and varied to be explored at random, that map is as essential as observation and experiment to science’s continuing development” (Kuhn 1970, 109). Like all knowledge systems, science offers simplified and partial maps of some aspects of the real world. But it is *not* the same as reality.

A last-ditch attempt to preserve the idea that science *can* provide an accurate account of reality is the delightful no-miracles argument advanced by the philosopher Hilary Putnam (b. 1926). Putnam argued that if a theory works, then the simplest explanation of that fact is to assume that the theory provides a good description of the real world. On this argument, it is the success of modern science that justifies its claims to provide accurate descriptions of reality. As Putnam puts it, “The positive argument for realism [the doctrine that science provides an accurate description of the real world] is that it is the only philosophy that does not make the success of science a miracle” (Psillos 1999, 71).

The apparent impossibility of finding any rigorous way of defining what is distinctive about modern science suggests that science may not be as different from other systematic forms of knowledge as is often supposed. All knowledge systems, even those of animals, offer maps of reality that provide more or less accurate guides to material reality. Perhaps, as the historian Steven Shapin has argued, the scientific revolution does not mark as clear an epistemological break as was once assumed. Most seventeenth-century scientists were well aware of the continuities between their ideas and those of the medieval and ancient worlds. Indeed, Newton, like many other scientists of his epoch, continued to study alchemy even as he was laying the foundations of what many think of today as true science. Even the notion of a scientific revolution is a modern idea; the phrase was first coined in 1939, by the philosophical historian Alexandre Koyré (1892–1964).

Developments in the twentieth century have done even more to blur the distinction between modern science and other systematic forms of knowledge. Quantum physics and chaos theory have shown that

Sculpture depicting an early Chinese invention, the magnetic compass. The spoon-shaped needle (lodestone) is made from magnetic oxides. Anticipations of modern scientific thought can be found in many ancient societies, from China to Mesoamerica.

reality itself is fuzzier than was once supposed, a conclusion that has forced scientists to abandon the nineteenth-century hope of attaining a mechanically perfect description of reality. As a result, the differences between the sciences and the social sciences appear much less clear-cut than they once did. This is particularly true of historical scientific disciplines, such as cosmology or biology. Insofar as they try to describe changes in the past, specialists in these fields face the same dilemmas as historians; far from basing conclusions on repeatable laboratory experiments, they try, like historians, to reconstruct a vanished past from fragments left randomly to the present.

As the borders between the sciences and other modern disciplines have blurred, the idea of science as a quite distinct form of knowledge has become harder to defend. Careful observation leading to technological innovation is a feature of most human societies, while general theories about the nature of reality are offered in most forms of religion. Inductivist and falsificationist arguments cannot prove the truth of science; at best they highlight the pragmatic fact that scientific theories work because they are based on a larger body of observational evidence than any earlier knowledge systems and are also subject to exceptionally rigorous truth tests.

That line of argument suggests that we examine modern science's place in human life historically, seeing modern science as one of many different human knowledge systems that have evolved in the course of world history. From this perspective, it is striking how, over time, human knowledge systems have had to incorporate more and more information, and how the task of distilling that information into coherent theories has required ever more stringent testing of ideas and yielded theories that were increasingly universal and abstract in their form though increasingly elaborate in their details. Perhaps, then, the main distinguishing feature of modern science is its scale.

As Andrew Sherratt (1995) puts it: "‘Intellectual Evolution’ . . . consists principally in the emergence of modes of thinking appropriate for larger and larger human groupings . . . This transferability has been manifested in the last five hundred years in the growth of science, with its striving for culture-free criteria of acceptance . . ." Because it is the first truly global knowledge system, modern science tries to explain a far greater volume and variety of information, and it subjects that information to far more stringent truth tests than any earlier knowledge system.

This approach may help explain the two other distinctive features of modern science: its astonishing capacity to help us manipulate our surroundings and

Henry Stacy Marks, *Science is Measurement* (1879). Oil on canvas. Scientists base their claims on careful and systematic analysis of evidence.

rigorous avoidance of anthropomorphic explanations. For most of human history, knowledge systems were closely linked to particular communities, and as long as they provided adequate explanations of the problems faced by those communities, their credibility was unlikely to be challenged. But their limitations could be exposed all too easily by the sudden appearance of new problems, new ideas, or new threats. This was what happened throughout the Americas, for example, after the arrival of European conquerors, whose ideas undermined existing knowledge systems as effectively as their diseases and military technologies undermined existing power structures. As the scale of human information networks widened, attempts to integrate knowledge into coherent systems required the elimination of culture-specific explanations and encouraged reliance on abstract universals that could embrace larger and more diverse bodies of information and that could appeal to more diverse audiences.

As the sociologist Norbert Elias (1897–1990) wrote in an elegant account of changing concepts of time, “The double movement towards larger and larger units of social integration and longer and longer chains of social interdependencies . . . had close connections with specific cognitive changes, among them the ascent to higher levels of conceptual synthesis” (Elias 1998, 179). The change can be seen clearly in the history of religions. As religious systems embraced larger and larger areas, local gods were increasingly supplanted by universal gods claiming broader and more general powers and behaving in more law-like and predictable ways than the local gods they displaced. Eventually, the gods themselves began to be displaced by abstract, impersonal forces such as gravity that seemed to work in all societies, irrespective of local religious or cultural beliefs.

The Emergence and Evolution of Science

The knowledge systems of the animal world are individualistic; each individual has to construct its own maps of reality, with minimal guidance from other members of its species. Humans construct their knowledge systems collectively because they can swap information so much more effectively than other animals. As a result, all human knowledge systems distill the knowledge of many individuals over many generations, and this is one reason why they are so much more effective and more general in their application than those of animals.

This means that even the most ancient of human knowledge systems possessed in some degree the qualities of generality and abstraction that are often seen as distinguishing marks of modern science. Frequently, it seems, the knowledge systems of foragers relied on the hypothesis that reality was full of conscious and purposeful beings of many different kinds, whose sometimes eccentric behavior explained the unpredictability of the real world. Animism seems to have been widespread, and perhaps universal, in small-scale foraging communities, and it is not unreasonable to treat the core ideas of animism as an

attempt to generalize about the nature of reality. But foraging (Paleolithic) era knowledge systems shared more than this quality with modern science. There are good *a priori* reasons to suppose that foraging communities had plenty of well-founded empirical knowledge about their environment, based on careful and sustained observations over long periods of time. And modern anthropological studies of foraging communities have demonstrated the remarkable range of precise knowledge that foragers may have of those aspects of their environment that are most significant to them, such as the habits and potential uses of particular species of animals and plants. Archaeological evidence has also yielded hints of more systematic attempts to generalize about reality. In Ukraine and eastern Europe engraved bones dating to as early as thirty thousand years ago have been found that appear to record astronomical observations. All in all, the knowledge systems of foraging societies possessed many of the theoretical and practical qualities we commonly associate with modern science. Nevertheless, it remains true that the science of foragers lacked the explanatory power and the universality of modern science—hardly surprising given the limited amount of information that could accumulate within small communities and the small scale of the truth markets within which such ideas were tested.

With the appearance of agricultural technologies that could support larger, denser, and more varied communities, information and ideas began to be exchanged within networks incorporating millions rather than hundreds of individuals, and a much greater diversity of experiences and ideas. By the time the first urban civilizations appeared, in Mesopotamia and Egypt late in the fourth millennium BCE, networks of commercial and intellectual exchange already extended over large and diverse regions. Mesopotamia and Egypt probably had contacts of some kind with networks that extended from the Western Mediterranean shores (and perhaps Neolithic Europe) to Sudan, northern India, and Central Asia, in what some authors have described as the first world system.

Calendrical knowledge was particularly important to coordinate the agricultural activities, markets, and public rituals of large and diverse populations. The earliest calendars distilled a single system of time reckoning from many diverse local systems, and they did so by basing time reckoning on universals such as the movements of the heavenly bodies. This may be why evidence of careful astronomical observations appears in developed Neolithic societies in Mesopotamia, China, Mesoamerica (whose calendars may have been the most accurate of all in the agrarian era), and even in more remote environments such as England (as evidenced by Stonehenge) or Easter Island. The development of mathematics represents a similar search for universally valid principles of calculation. It was stimulated in part by the building of complex irrigation systems and large monumental structures such as pyramids, as well as by the need to keep accurate records of stored goods. In Mesopotamia, a sexagesimal system of calculation was developed that allowed complex mathematical manipulations including the generation of squares and reciprocals.

In the third and second millennia BCE, Eurasian networks of commercial and information exchanges reached further than ever before. By 2000 BCE, there existed trading cities in Central Asia that had contacts with Mesopotamia, northern India, and China, linking vast areas of Eurasia into loose networks of exchange. Late in the first millennium BCE, goods and ideas began traveling regularly from the Mediterranean to China and vice versa along what came to be known as the Silk Roads. The scale of these exchange networks may help explain the universalistic claims of religions of this era, such as Zoroastrianism, Buddhism, and Christianity.

The impact of these developments on knowledge systems is easiest to see in the intellectual history of classical Greece. Here, perhaps for the first time in human history, knowledge systems acquired a new degree of theoretical generality, as philosophers tried to construct general laws to describe the real world. As the writings of the historian Herodotus suggest, the Greeks were exposed to and interested in a colossal variety of different ideas and influences, from

Gentility of character, and nicety and purity of mind, are found in those who are capable of thinking deeply about abstruse matters and scientific minutiae. • **al-Razi (864–930)**

North Africa, Egypt, Persia, India, and the pastoralist societies of the steppes. The volume and variety of ideas to which Greek societies were exposed reflected their geographical position and the role of Greek traders, explorers, and emigrants forced, partly by overpopulation, to explore and settle around the many different shores of the Mediterranean and the Black Sea. Faced with a mass of new information, Greek philosophers set about the task of eliminating the particular and local and isolating those ideas that remained true in general. Thales of Miletus (c. 625–547 BCE), often regarded as the first of the Greek natural philosophers, offered explanations of phenomena such as earthquakes and floods that are universal in their claims and entirely free of the notion that reality is controlled by conscious entities.

At its best, Greek natural philosophy tried to capture not just this or that aspect of reality, but reality's distilled essence. This project is most apparent in Greek mathematics and in Plato's conviction that it is possible to attain knowledge of a perfect real world beneath the imperfections of the existing world. Greek philosophers were particularly interested in the testing of new ideas, a trait that is perhaps inevitable in societies faced with a sudden influx of new forms of knowledge. The rigor with which ideas were tested is apparent in the dialogues of Socrates, in which ideas are repeatedly subjected to Socrates' corrosive logic (in an ancient anticipation of the notion of falsification), with only the most powerful surviving. Many other societies developed sophisticated methods of mathematical calculation and astronomical observation, and some, such as Song China (960–1279), developed metallurgical, hydraulic, and financial technologies that were unsurpassed until the twentieth century. But few showed as much openness to new ideas or as much interest in the testing of new ideas and theories as the Greeks.

Other societies have responded in similar ways to the exposure to new and more varied ideas. Perhaps Mesopotamia and Egypt, both with relatively easy access to Africa, India and the Mediterranean, count as early pioneers of scientific ideas for similar reasons. And perhaps it is the extensive contacts of medieval

Islam that explain the fundamental role of Islam both in exchanging ideas (such as the mathematical concept of zero) between India and the Mediterranean worlds and in preserving and developing the insights of Greek and Hellenic science. Even in the Americas, it may have been the size of Mesoamerican populations and their exposure to many different regional cultures that led to the development of sophisticated calendrical systems from perhaps as early as the second millennium BCE.

Europe in the era of the scientific revolution certainly fits this model. Medieval European societies showed a remarkable openness to new ideas and an exploratory spirit that was similar to that of classical Greece. By the late medieval ages, European contacts reached from Greenland in the west to China in the east. Then, as European seafarers established close links with Southeast Asia in the east and the Americas in the west, Europe suddenly found itself at the center of the first global network of informational exchanges. The unification of the world in the sixteenth century constituted the most revolutionary extension of commercial and intellectual exchange networks in the entire history of humanity. Ideas about navigation and astronomy, about new types of human societies and new gods, about exotic crops and animal species, began to be exchanged on an unprecedented scale. Because Europe suddenly found itself at the center of these huge and varied information networks, it was the first region of the world to face the task of integrating information on a global scale into coherent knowledge systems. In the sixteenth century, European philosophers struggled to make sense of the torrent of new information that descended upon them, much of which undermined existing certainties. Like the Greeks, European thinkers faced the challenge of sorting the ephemeral from the durable, and to do that they had to devise new methods of observing and testing information and theories. It was this project that yielded the observational and experimental techniques later regarded as the essence of scientific method.

Thinkers in the era of the scientific revolution not only developed new ways of studying the world, they

also created a new vision of the universe. The new vision was based on the work of three astronomers: Nicholas Copernicus (1473–1543), Tycho Brahe (1546–1601), and Johannes Kepler (1571–1630). Copernicus was the first modern astronomer to suggest that the earth might be orbiting the sun; Brahe's careful astronomical observations provided the empirical base for Copernicus's theories, and Kepler's calculations showed that the new model of the universe worked much better if it was assumed that heavenly bodies traveled in ellipses rather than circles. Galileo used the newly invented telescope to show that heavenly bodies were as scarred and blemished as the earth, an observation that raised the intriguing possibility that the heavens might be subject to the same laws as the earth. Newton clinched this powerful unifying idea by showing that both the earth and the heavens—the very small and the very large—were subject to the same basic laws of motion. And this suggested the possibility that the universe as a whole might run according to general, abstract laws rather than according to the dictates of divine beings. Galileo's discovery of millions of new stars also suggested that the universe might be much larger than had been supposed, while Anthony van Leeuwenhoek (1632–1723), the pioneer of modern microscopy, showed that at small scales there was also more to reality than had been imagined. Taken together, the theories of the sixteenth and seventeenth centuries transformed traditional views of the universe in ways that threatened to decenter human beings and throw into question God's role in managing the universe. It was no wonder, then, that many feared that the new science might undermine religious faith.

Since the seventeenth century, the global information exchanges that stimulated the scientific breakthroughs of the scientific revolution have accelerated and affected more and more of the world. The prestige of the new sciences was particularly high in the era of the Enlightenment (seventeenth and eighteenth centuries), and encouraged more and more investigators to study the world using the techniques and assumptions of the scientific revolution. In the eighteenth and nineteenth centuries, scientific investigations yielded

U.S. president Warren G. Harding escorts Madame Curie down the steps of the White House in the 1920s.

powerful new theories in fields as diverse as medicine (the germ theory), chemistry (the atomic theory and the periodic table), the study of electromagnetism (the unified theory of electromagnetism), energetics (theories of thermodynamics), geology, and biology (natural selection).

Scientific research was supported by the creation of scientific societies and journals, the introduction of science courses in universities, and the creation of research laboratories by businesses. The last two developments were both pioneered in Germany. The word *scientist* was first used in the 1840s. Meanwhile, the spread of scientific approaches to the study of reality and the increasing scope of scientific theory began to yield significant technological innovations in health care, manufacturing, and warfare. Particularly important were innovations in transportation and communications, such as the invention of trains and planes and the introduction of postal services, the telegraph, the telephone, and eventually the Internet, because these innovations expanded the scale and quickened the pace of information exchanges.

In the twentieth century, a series of new scientific theories appeared that refined the orthodoxies

Nine scientists in the Tian Shan range in Central Asia observe a solar eclipse through two telescopes (1907).

of eighteenth- and nineteenth-century science. Einstein's theory of relativity demonstrated that space and time were not absolute frames of reference, while the quantum theory showed that, at the very smallest scales, reality itself does not behave in the predictable, mechanical ways assumed by earlier theories. Big bang cosmology, which has dominated cosmological thought since the 1960s, demonstrated that the universe, far from being eternal and infinite, had a history, beginning many billions of years ago, while the theory of plate tectonics, which appeared at about the same time, provided the foundations for a unified theory of geology and a detailed history of the formation and evolution of the earth. In biology, Francis Crick (1916–2004) and James Watson (b. 1928) described the structure of DNA in 1953; their work laid the foundations for modern evolutionary theory and modern genetic technologies. Meanwhile, the scale of scientific research itself expanded as governments and corporations began to fund special research facilities, sometimes to fulfill national objectives, as was the case with the Manhattan Project, which designed the first atomic weapons.

Outlook

Recent scholarship suggests that it is a mistake to see modern science as fundamentally different from all other knowledge systems. Like all effective knowledge systems, it is based on induction: on careful empirical observation followed by attempts to generalize. Like all knowledge systems, it is subject to falsification, to the sudden appearance of new realities or new forms of information that may overturn established certainties. What really distinguishes modern science from earlier knowledge systems is the size of the intellectual arena within which its ideas are generated and tested. Its explanatory power and its qualities of abstraction and universality reflect the volume and diversity of the information it tries to distill, and the rigor of the truth tests to which its claims are subjected in a global truth market.

During the past two centuries, science has spread beyond the European heartland to Russia, China, Japan, India, and the Americas. Today it is a global enterprise, and its accounts of reality shape the outlook of educated people throughout the world. Far

from diminishing, the flow of new information that stimulated the original scientific revolution has kept expanding as the pace of change has accelerated and the world as a whole has become more integrated. Early in the twenty-first century, the power of science to generate new ways of manipulating the material world, for better or worse, shows no sign of diminishing. Science has given our species unprecedented control over the world; how wisely we use that control remains to be seen.

Scientific Instruments

All scientific instruments share a single quality: they are made and used to study the natural world or to tell others about the natural world. Too often, say some scholars (and museum curators faced with cabinets full of compasses and sextons) we lose focus on how and for what purposes objects are used, and by whom, and that those parameters often vary from culture to culture.

We think that we know what “scientific instruments” are. After all, science museums all over the world proudly display collections of the material remains of the activity called “science.” Scientific instruments include astrolabes and armillary spheres, chemical glassware and fume cupboards, telescopes and clocks. They are used in laboratories, classrooms, in space, at sea and underground—and many other places besides—and vary in size from massive objects like the particle accelerator at CERN, Geneva, to the tiniest nanotechnology devices that can only be seen with the help of a microscope. They might look impressive, like the gilt brass telescopes of eighteenth-century European observatories, or they might be deceptively plain, functional and compact black boxes packed with electronic circuitry. What links all these instruments is that they were made and used to study the natural world or to tell others about the natural world: activities common to many world cultures. But the custodians of these collections sometimes have trouble defining what to include under the heading “scientific instruments” and therefore what to collect. Deborah Warner, a curator at the Smithsonian Institution in Washington, DC, in an article entitled “What Is a Scientific Instrument,

When Did It Become One, and Why?,” explores the changing meanings of the term *scientific instrument* and concludes that the term is problematic. She says that it should not be used as often as it is and should be replaced by terms contemporary with the instruments that are being studied.

Albert Van Helden and Thomas L. Hankins also discuss the ambiguity of the term *scientific instrument* in their introduction to a collection of essays entitled *Instruments*, suggesting that the ambiguity inherent in the terms *science* and *instrument* might be a virtue. They believe that we should look at the variety and contexts of the uses of such instruments rather than make a list of which kinds of objects we are to count as scientific instruments. They list four uses to which instruments are put. First, Van Helden and Hankins point out that instruments confer authority and settle disputes—instruments are part of the attempts by practitioners to convince others of the validity of their ideas. Second, and linked to the first use, Van Helden and Hankins point out that instruments are created for audiences, that is, the wider community, including patrons and supporters, who is interested in the practitioners’ activities. Third, Van Helden and Hankins suggest that one use of instruments is to act as a bridge between natural science and popular culture, through the symbolic and educational uses of objects. Fourth, Van Helden and Hankins note that the role of instruments changes when they are used to study living things. In none of these four uses is there an explicit statement that people use instruments to find out about the natural world, but this use is the underlying idea behind the other four: instruments provide ways of looking at, understanding, and telling others about the natural world.

Recent work in the sociology of scientific knowledge has shown that the actual processes of (Western) scientific researchers and their use of instruments are less objective than the third-person, passive-voiced articles reporting their results would have the reader believe. The role of skill and tacit knowledge looms large, and especially so in the use of instruments. Thus, if in the much better-studied case of Western scientific investigation we have much to learn about the ways that people use objects to find out about the natural world, in other world cultures we have even more to learn.

Helene Selin, editor of the *Encyclopedia of the History of Science, Technology and Medicine in Non-Western Cultures*, believes that to study science in non-Western cultures we must accept that each culture has its own science that defines and predicts natural events and that each science is valid in terms of its culture. She contends that our own science also is a reflection of its culture and that culture is a factor in each step of doing science.

Acknowledging the Western focus of most scholarship on scientific instruments, Van Helden and Hankins suggest that, “Looking at instruments in a non-Western society teaches us that their use and intended purpose is not obvious, and warns us, by reflection, that the role of instruments in Western science is sure to be even more complex . . .” (Van Helden and Hankins 1994, 6).

They suggest that we look at how scientific instruments have worked in humanity’s consideration of the natural world—the different uses to which objects have been put. In Selin’s terms, we must look at how instruments have worked within the different frameworks that she calls “science”—the ways that people consider and have considered the natural world.

This focus on how objects are used, by whom, and for what purposes means that we can see objects that are superficially similar in function but that relate to people and their activities in quite different ways. For example, navigation at sea in eighteenth-century Europe relied on using charts, taking measurements of the altitude of sun and stars above the horizon and the direction of the North Pole—activities linked

to instruments such as the compass and the mariner’s astrolabe. Turning to the Marshall Islands in the South Pacific, we find charts made from sticks that map the atolls (coral islands consisting of a reef surrounding a lagoon) and islands, waves and currents, and measurement of direction based on a star compass. But the ways that these objects are used by the Marshall Islanders are different from the ways that the European charts and compass were used, most significantly in that the Marshall Islanders do not take the charts and star compass to sea with them. The islanders use the charts in the training of navigators rather than in the practice of navigation itself—someone memorizes the charts and the star compass, and the navigation is actually done using mental models of the physical objects.

Cultural Context

The function of scientific instruments can also change as they move from one cultural context to another. During the sixteenth and seventeenth centuries Jesuit missionaries visited China, hoping that by convincing the emperor of the superiority of their astronomical instruments and observations, they could persuade him to convert to Catholicism. The Jesuits took with them the instrument designs of the Danish astronomer Tycho Brahe and taught Chinese metalworkers to make instruments according to these designs, albeit with Chinese-style stands and mounts. These new instruments replaced the thirteenth-century astronomical instruments of the Beijing (Peking) observatory. In his study of astronomical instruments in Ming-dynasty China (1368–1644), Thatcher Deane argues that they were more “useful” as symbols for the emperor’s heavenly mandate than as tools for observation. Allan Chapman’s study of the Jesuit missions to China shows that they did not need to use the most up-to-date instrument designs because their role was more ambassadorial than observational. Thus, the status of the instruments used by the Jesuits changed subtly when physically (and intellectually) located in China rather than in Europe. The Jesuits hoped that this integration could, in the end, lead to the

conversion of the Chinese emperor, but the Chinese were happy to select certain benefits offered by the missionaries and take their astronomical and instrumental expertise without following their lead in matters of religion.

The Jesuit missionaries' attempts to convince the Chinese of the superiority of European astronomical (and, by extension, religious) thinking offer an example of the use of scientific instruments in the service of religious conversion. But, as the historian of technology Michael Adas describes, despite the fact that scientific curiosity was a major motivating factor in the Europeans' exploration of the world from the fifteenth century onward, the early explorers and conquistadors did not often use scientific knowledge as a way of gauging their superiority over the people they encountered; that came later with the rise of "scientific racism." Nonetheless, the existence of large cities or complex scientific instruments was included in assessments about how "developed" a particular civilization was. As empire and colonialism gathered pace, division of "science" from "magic" and "superstition" sealed the Western dominance of science and technology, and this edifice is only now being slowly dismantled, with renewed interest in scientific and medical knowledge of non-Western civilizations.

The place of scientific instruments within the process of colonialism is complex. For example, surveying instruments are used in the construction of maps, and evidence indicates that mapmaking was among the strategies used by colonial powers to delineate and therefore control the land they occupied. We might know a little about how, say, Native Americans mapped their world, but we often have little or no evidence to tell us for sure what relationship instruments had to their study of the natural world. Selin cautions against seeing the lack of evidence as a lack of activity, arguing that surely mathematicians in the Pacific Island countries or the Americas were as skillful as more famous people from China or the Middle East. The survival of written records is contingent on many factors, not least on war and colonialism, and because of this fact the study of objects becomes even more important: they provide a source of knowledge about

This pen-and-ink rendering depicts equipment in the Paris Observatory in the early twentieth century.

people and their scientific activities that is outside written records and therefore accessible to scholars in cases where the evidence is otherwise somewhat thin or even completely lost.

Questions

These few examples show the diversity of ways by which people have used instruments to consider the natural world and the ways in which some scholars have studied them. Instruments can relate to the underlying scientific framework and practices in various ways. Therefore, the problems identified by Warner and by Van Helden and Hankins loom larger when we consider scientific instruments as part of world history. After all, what is to count as a "scientific instrument" when the very category of "science" is opened up to include all the ways by which people measure, predict, and tell others about the natural world? The term is loaded with Western ideals about

the rational, impartial approach to the natural world, which might be difficult to reconcile with other peoples' ways of considering the heavens, the rocks, or the seas. A stick in the ground might be just that, but a stick in the ground casts a shadow, and if someone uses the track of that shadow to measure the passage of time or the seasons, that stick becomes a sundial or a calendar. Should we then call it a "scientific instrument"? Should a museum include that stick in its collection of scientific instruments? If it did, what other information should it record about the ways by which the stick was used so that the link between object and practice is not lost?

Some objects might be classified as scientific instruments all the time—such as an armillary sphere, which models the structure and motions of the heavens. However, even such apparently intrinsically scientific instruments can be used for symbolic or religious purposes wider than the strictly "scientific." Other objects might have the status of "scientific instrument" only temporarily, such as the stick in the ground. Here we have gone far beyond the first explicit definition of the term *scientific instrument*, proposed by the Scottish physicist James Clerk Maxwell in 1876: "Everything which is required in order to make an experiment is called Apparatus. A piece of apparatus constructed specially for the performance of experiments is called an Instrument" (Maxwell 1876, 1).

We have perhaps gone too far for the comfort of some museum curators because allowing objects to temporarily have the status of "scientific instruments" brings in huge numbers of objects that have thus far not been collected or studied as such. If this definition is pushed to its limits, curators such as Warner will have even greater problems determining what is to count as a scientific instrument and therefore what kinds of objects to collect. People interested in how humans look at the natural world and how objects and instruments relate to that activity, though, are less constrained by the practical and physical problems of conservation and storage, and such a broad definition is perhaps less problematic. It might be

even beneficial because it opens our eyes to the different approaches that humans have taken to understanding the natural world and the various roles that instruments have played in these activities.

Scientific Revolution

The Scientific Revolution marked a period of monumental change in thought, belief, and cultural and institutional organization that swept Europe between roughly 1550 and 1700. During those 150 years Western science advanced more than it had during the previous fourteen hundred years—since the Greek physician Galen’s work in anatomy and the Greek astronomer Ptolemy’s work in planetary motion.

Historians generally date the beginning of the Scientific Revolution, the period that produced the most remarkable advances made in Western science for more than a millennium, with the Polish astronomer Nicolaus Copernicus (1473–1543) and his book *De Revolutionibus* (On the Revolutions) and date the ending with the English mathematician and physicist Isaac Newton (1642–1727) and his book *Philosophiae Naturalis Principia Mathematica* (Mathematical Principles of Natural Philosophy).

Before Copernicus and Newton people still saw the world through the eyes of the Greek philosopher Aristotle (384–322 BCE). He thought that the world is composed of four elements: earth, water, air, and fire. The Aristotelian world was a hierarchically structured universe where a clear distinction existed between the destructible space under the moon and eternal celestial space. Because to minds of the time Aristotelian philosophy could answer the most important cosmological (relating to the natural order of the universe) and astronomical questions, people found no compelling reason to dispute him for centuries. His natural philosophy had been accepted—with slight modifications—in the Western world by both intellectuals and the “working” class, by both

pagans and Christians, for almost two thousand years.

Nevertheless, as Western thought gradually began to change during the Scientific Revolution, some scientists—a handful at first, fistfuls after a while—published works that challenged Aristotelian philosophy. According to the French historian Alexandre Koyre (1892–1964), two fundamental changes occurred during the Scientific Revolution: the previous view of the universe was destroyed, and space was geometricized. “[The founders of modern science] had to destroy one world and to replace it by another. They had to reshape the framework of our intellect itself, to restate and to reform its concepts, to evolve a new approach to Being, a new concept of knowledge, a new concept of science” (Koyre 1968, 20–21).

The world during the Scientific Revolution became an open and infinite universe without any hierarchy. It could be described using the geometry of the Greek Euclid. Celestial phenomena and earthly phenomena were now described by the same physical laws.

Furthermore, scientists were not satisfied with just describing natural phenomena but went further by studying the secrets of nature to explain how nature works. As they worked toward this goal they needed more powerful tools than purely philosophical arguments and therefore began to use mathematics and experiments.

Such a transition was not easy, its course not straight and smooth. Many times the scientists who played a major role in the transition lost their enthusiasm, had doubts, and balked. Isaac Newton, for example, had been passionately engaged in alchemy (a medieval chemical science aiming to achieve the transmutation of base metals into gold), and the German astronomer

Portrait of Copernicus from the ephitaphium in St. John Basilica, Toruń, Poland, circa 1580.

Johannes Kepler (1571–1630) had to summon great inner strength to transform his thinking from animism (a doctrine that the vital principle of organic development is immaterial spirit) to what we call today “mechanistic” thinking, which holds that natural processes are mechanically determined and capable of explanation by laws of physics and chemistry.

Furthermore, the Scientific Revolution was not an achievement of just a few brilliant minds who conceived and codified new theories and discoveries and made them available to a wider and more receptive audience. The academies and learned societies—such as the Royal Society of London (1692), the Academy of Sciences in Paris (1666), the St. Petersburg Academy (1729), and the Royal Academy of Sciences in Denmark (1742)—played a significant role as the institutions that legitimate such new ideas. Universities remained more conservative, continuing to support Aristotelian philosophy.

During the Scientific Revolution thinkers also began to channel knowledge into rational systems. For

example, in biology the Swedish botanist Carolus Linnaeus (1707–1778) devised the Linnean classification system, which catalogued all known living creatures into a system that defined their morphological (relating to form and structure) relations. In chemistry a new system of understanding chemicals and elements began when the English scientists Henry Cavendish and Joseph Priestley discovered gases during the latter half of the eighteenth century. In medicine physicians began to understand that the body is a natural system that functions predictably, like a machine. Disease is simply the breaking down of the machine. The science of pathology began, and physicians began to see disease—and recovery from disease—as a rational process.

Copernicus

The astronomer Nicolaus Copernicus boldly claimed that the Earth rotates on its axis daily and revolves around the sun (heliocentric) annually rather than being fixed in the center of the cosmos. Such a claim ran counter to tradition, to the authority of the ancients, and to views of both colleges and churches.

Although relevant ideas had been expressed in antiquity, for example, by the Greek Pythagorean philosopher Philolaos (flourished 475 BCE) and the Greek astronomer Aristarchus (320–250 BCE), Copernicus was the first to attempt to prove the mathematical foundations of the heliocentric system using geometry.

However, for several decades the theories of Copernicus failed to solve some important astronomical problems, such as the orbits of the planets and gravity.

Galileo

The Italian astronomer Galileo Galilei (1564–1642) was the first scientist to formulate the law of the free fall of bodies. According to this law a body that falls from a certain height without friction has constant acceleration, and the distance it covers is relevant to the square of the time that is needed. Galileo formulated

Pages from Copernicus's book *De Revolutionibus* (*On the Revolutions*). Beinecke Rare Book and Manuscript Library, Yale University.

this law in 1604 and made it public in 1632 in his book *Dialogo sopra I due Massimi Sistemi del Mondo* (Dialogues of the Two Chief Systems of the World). He described the law in detail in 1638 in his book *Discorsi e Dimostrazioni Matematiche intorno a due nuove scienze attenenti alla Mecanica e I movimenti locali* (Speeches and Mathematical Demonstrations around Two New Sciences Pertaining to Mechanics and Local Movements).

According to tradition Galileo proved the accuracy of the law with experiments that he performed in the Tower of Pisa, but historical evidence has not fully supported that tradition. On the contrary, he performed experiments using an inclined plane that had been constructed to minimize friction.

Furthermore, Galileo clarified the concept of inertia and expressed it in a form that was not far from the form of the law of inertia that Newton proposed later.

Galileo also was among the first scientists to use a telescope to observe the heavens. He presented one

of his first telescopes to the doge (chief magistrate) of Venice, asking that Galileo's professorship be made permanent at the University of Padua and receiving a doubling of his salary.

Galileo's observations of the surface of the moon and the satellites of Jupiter, published in 1610 in *Sidereus Nuncius* (Sidereal Messenger), supported the Copernican system. Many scientists disputed these observations, however, and questioned the reliability of observations made with a telescope.

To win over such skeptics Galileo used a clever stratagem: he sent his book and a telescope to members of the nobility to gain their political support. But the Catholic Church finally forced Galileo to renounce Copernicus's system, and tradition says that after his renunciation Galileo whispered "yet it moves."

Kepler

The astronomer Johannes Kepler published his book *Mysterium Cosmographicum* (The Secret of the

Title page from *Principia Mathematica* by Sir Isaac Newton, Cambridge, 1713. Beinecke Rare Book and Manuscript Library, Yale University.

Universe) in 1596. When he realized that his theory about the movements of the planets Mercury and Saturn was wrong he began to try to improve the accuracy of his observations. For this reason in 1600 he became an assistant to the Danish astronomer Tycho Brahe (1546–1601), who established the regular observation of stars and planets on the sky. When Brahe died in 1601 Kepler possessed a huge amount of astronomical observations. From them he finally formulated his famous three astronomical laws: (1) The orbits of the planets are ellipses, with one of their foci the sun. (2) A line joining a planet and its star sweeps out equal areas during equal intervals of time. (3) The square of the sidereal period of an orbiting planet is directly proportional to the cube of the orbit's semimajor axis.

The first two laws were published in 1609 in Kepler's book *Astronomia Nova* (New Astronomy), which shows Kepler's transition from animistic to mechanistic thought.

Newton

Isaac Newton's contributions to the Scientific Revolution were many and included his mechanical universe and his universal laws. His *Philosophiæ Naturalis Principia Mathematica* was possibly the most influential scientific book ever published. It contained his laws of motion, which formed the foundation of classical mechanics, as well as his law of universal gravitation. Many scholars also credit Newton with inventing calculus.

The mechanistic concept was the mainstream of scientific thought during the seventeenth century. The concept's most important representative was the French mathematician and philosopher René Descartes (1596–1650). He argued that matter is everywhere in the universe and proposed his vortex theory to explain the movement of celestial bodies. He believed that fine matter in the ether forms vortices around the sun and other stars. Although science would prove Descartes's theory inadequate, its contribution was important because eventually no one would cite supernatural powers to explain physical phenomena.

Such advances created the necessary setting for the next decisive step—the synthesis of a new view of the world. The person most prominent in creating this new view was Newton, who believed that the orbits of the planets are determined by a central force that is reduced in inverse proportion with the square of the distance.

Most people learned about Newton's ideas indirectly by reading the books of the so-called popularizers of Newtonian physics. People have difficulty understanding *Principia* even today. The proofs of the various proposals and theorems follow traditional geometrical methodology, providing the necessary reliability in the framework of his contemporary scientific community.

Principia states the three basic laws of classical physics: the principle of inertia, the principle of action-reaction, and the second law of mechanics, according to which acceleration is proportional to the force acting on a body. Furthermore, Newton defines the law of universal attraction and uses it to

determine the orbits of the planets. In another book, *Optics* (1704), Newton presents his ideas on light. This book is characterized by its persistence on experimental methodology.

The Dutch mathematician Christian Huygens (1629–1695) and the German philosopher and mathematician G. W. Leibniz (1646–1716) objected to many Newtonian propositions, but their objections did not diminish the wider acceptance of Newton's work.

Dissemination

Many historians feel that the Scientific Revolution was not fully propagated until the eighteenth century. For example, that was when Dutch engineer Peter van Musschenbroek (1692–1761) and the Italian philosopher Francesco Algarotti (1712–1764) undertook the task of making Newton's work better known. Newton's work connected closely with the Enlightenment, which was a philosophic movement of the eighteenth century that was marked by a rejection of traditional social, religious, and political ideas and an emphasis on rationalism.

Among others the French man of letters Bernard Fontenelle (1657–1757) supported the idea that the new scientific method could be applied in politics, ethics, and sociology and that it could be used to determine human behavior in a rational way. In this setting Denis Diderot (1713–1784) and Jean le Rond d'Alembert (1717–1783) produced their famous French encyclopedia.

By the end of the eighteenth century the main physical theories of the Scientific Revolution were spreading in countries such as Spain, Portugal, Brazil, and Greece as conservatives abandoned their resistance to the new worldview.

As a result of this transformation, during the last quarter of the eighteenth century two other revolutions took place in France. One was political, leading to publication of the Declaration of the Rights of Man and of the Citizen in 1789, and one was scientific, transforming chemistry from an alchemical practice into a real science. The French chemist Antoine

Newton's *Principia* states the three laws of classical physics: inertia; action-reaction; and the second law of mechanics.

Lavoisier (1743–1794) played a role in both revolutions, being an opponent of the first and a leader of the second.

The Scientific Revolution was crucial for the development of what we call today "Western civilization." Its intellectual advances were the embodiment of humanity's quest to gain a coherent grasp of nature.

The process of script decipherment involves figuring out how to interpret an alphabet that is no longer in use and completely forgotten. The most commonly recognized decipherments are cuneiform and hieroglyphs. The most recent (in 2008), the alphabet of a language called Carian (from southern Anatolia and throughout Egypt) depended on interpreting graffiti written by Carian mercenaries during the second half of the first millennium BCE.

For a script to be deciphered, it must first have gone out of use and been completely forgotten—along with the entire culture it supported. The language it wrote may or may not have survived, and related scripts may still be in use, but the script itself is the focus. Thus Etruscan is not a candidate for decipherment, since its alphabet, midway between the Greek and the Latin, is unproblematic. Nor, when an unknown Egyptian tomb is discovered, are its inscriptions deciphered, for they are written in a script that yielded its secrets nearly two hundred years ago. A decipherment is a discrete event, though subsequent generations of scholars may spend decades refining it.

The Semitic Consonantal Scripts

The first successful decipherment was achieved literally overnight in 1754 by Jean-Jacques Barthélemy,

an abbé and classical scholar who was numismatist to King Louis XV of France. Explorers brought back from the ancient city of Palmyra accurate copies of brief inscriptions displayed in pairs, Greek and Palmyrene, and it was an easy assumption that they represented the same content. Comparison of proper names yielded the pronunciations of the unfamiliar letters, and with hindsight both script and language could be seen to be similar to those of the closely related ecclesiastical literary Aramaic language, Syriac. Over the next few years Barthélemy was also able to interpret the more ancient but related numismatic and inscriptional Aramaic and Phoenician scripts as well. (The Phoenician language is closely related to Hebrew; along with Aramaic, they are Northwest Semitic languages.) Unfortunately from the point of view of historians, these materials virtually without exception are brief and uninformative, mainly funerary. Edward Gibbon in *The Decline and Fall of the Roman Empire* (1776) makes no use of them, for example, in his account of the fall of Palmyra and its queen Zenobia (chap. xi). Barthélemy himself, who spent thirty years preparing an immense picaresque didactic novel detailing *The Voyage of Young Anacharsis* (a fictional Phrygian traveler in mid-fourth-century Greece and environs), published in 1788, does not cite the inscriptions there.

Only in the second half of the nineteenth century did explorers and archeologists begin to encounter longer (mainly annalistic and dedicatory) inscriptions

 l-ak-ut-l-ak-d-en-a-es-o-is-et-qu-es-ok-l-or-d-e-i-ar-ok-es-ak-ur-iw-amak

A Cyprian inscription circa the fourth century BCE, with transliteration and Greek words below.

CHAPTER VIII

THE HISTORY OF THE CREATION OF THE GODS AND OF THE WORLD. VERSION A.

This and the following illustrations show decipherment and translation examples from *The History of the Creation of the Gods and of the World. Version A*, from Egyptian Hieroglyphics.

in these scripts, which began to provide alternative accounts of episodes known only from the Bible—the first, longest, and for a long time the earliest (c. 850 BCE) is the Mesha inscription (discovered 1868, in Moabite, very like Hebrew), which relates puzzlingly to 1–2 Kings; the Siloam Tunnel inscription (discovered 1880, in Hebrew) spectacularly illuminates 2 Kings 20:20. A handful of inscriptions in Aramaic from small Aramaean kingdoms scattered around the northeast corner of the Mediterranean—a perfectly preserved one was discovered in 2008 that may change our understanding of how its writers understood the concept of the soul—offer almost all that is directly known about these buffer states, located between the alternately surging Assyrian, Egyptian, and Hittite empires.

Antoine Isaac Sylvestre de Sacy's decipherment in the late 1780s of the scripts of the Middle Persian languages of the Parthian and Sasanian empires also did not yield much. From their coins and their meager

inscriptions, we learn little beyond the names of the kings and the fluctuating extents of their domains. Emil Rödiger's decipherment of the South Arabian ("Himyaritic") script a half-century later provided little information to historians. Inscriptions in the four languages involved, notably Sabaean, are numerous, and some are lengthy, but they are almost impossible to date, and they are concerned far more with local hydraulic projects than with affairs of state.

Cuneiform

By far the most important decipherment—not only in sheer quantity of materials made available, but in their quality as well—was of the complex of scripts known as cuneiform. Again it was a question of accurate copies, this time brought from Persepolis by the Danish explorer Carsten Niebuhr and published beginning in 1772. Each Persepolitan inscription appeared in three guises: three scripts differing in complexity. It was an easy surmise that they represented the same text in three languages; the crucial step in their decipherment was taken by a German *gymnasium* (high school) instructor, Georg Friedrich Grotefend, who in 1802 conjectured that the most prominent in each example, which also happened to be the simplest of the three, probably represented the principal language of the Persian (Achaemenid) Empire. Guided by de Sacy's texts, he expected to find formulas like "Xerxes, great king, son of Darius, great king, son of Hystaspes" (who was not a king)—the names known from the Greek of Herodotus. Indeed he found suitably repetitive patterns, and he knew enough of Iranian languages to point the way for specialists, some of the pioneers in Indo-European studies, including two other Danes, Rasmus Rask and Christian Lassen, to bring the decipherment to completion over the next few decades.

The Persepolis inscriptions proved to be singularly unenlightening as to political history, while theology and imperial ideology emerge more clearly. The only quasi-annalistic inscription, an immense one placed by Darius I on a cliff near Behistun, Iran, which was copied with great difficulty and aplomb by a British

military diplomat stationed in Baghdad, H. C. Rawlinson, offers endless opportunities for the disputations of historians. Its 1848 publication, however, was too late to be of use in the decipherment of cuneiform; Rawlinson's work on the Old Persian version seems to have independently replicated that of Grotefend over a generation earlier. The second of the three official Achaemenid languages, now known as Elamite, remains little understood (the initial interpretation was by yet another Dane, N. L. Westergaard). The third language—with by far the most complicated script ever deciphered—was the real historical bonanza. Though credit for its decipherment is usually assigned to Rawlinson, especially by his partisans toward the end of the nineteenth century, it is now clear that it was done by Edward Hincks, a Church of Ireland (Anglican) clergyman, whose better-known father was a professor in the university in Belfast and whose younger brother was Premier of Canada in the 1850s. His work was mainly published in the *Transactions of the Royal Irish Academy* in the late 1840s.

The inscribed materials in the third script that were available to Hincks had been brought from Mesopotamia to England as curiosities earlier in the nineteenth century, often identified by the names of their owners—the Bellino Stone, the India House Inscription—or had been published by explorers—notably a long inscription in a language now called Urartian from near Lake Van. An important tool in the decipherment was the presence in these inscriptions of repeated formulas that were spelled slightly differently (so as to fit in the available space, for instance). And the reason for repetitive formulas was that these long inscriptions turned out to be annals, with the events of successive years of a king's reign laid out in stereotypical form. The language of the Mesopotamian inscriptions (and the third Persepolitan variety) was soon identified as Semitic; it is now known as Akkadian. (Essentially the same writing system, devised for Sumerian, serves Akkadian, the Indo-European language Hittite, the not very well known Urartian and its only relative Hurrian, and the aforementioned Elamite, as well as other languages

of which only a few words are recorded.) True to the preoccupations of the time, in one of the very first editions of an ancient monument, the so-called Black Obelisk of Shalmaneser, Hincks was the first to recognize the name of a biblical personage, Jehu of the "house of Omri," king of Israel (1 Kings 16:16–28), among those paying tribute.

Throughout the 1840s the first excavations of sites in Mesopotamia—at ancient Nineveh—were carried out by Austen Henry Layard for the British Museum and Paul Émile Botta for the Louvre. Layard in particular had the good fortune to come across both a palace whose walls were covered with impressive reliefs and lavish inscriptions, and an extensive library, that of the Assyrian king Assurbanipal. Much of this material was shipped back to London, and the cuneiform tablets—shaped lumps of clay impressed by a stylus with characters composed of wedge-shaped

indentations—comprising the library that formed the nucleus of the British Museum's unsurpassed collection. (The Iraq Museum in Baghdad may possess more tablets, since it is the repository for all materials excavated in that country over the past many decades, but as the museum looting of spring 2003 made clear, they are far from fully catalogued, and the damage the collection may have sustained has not been fully assessed.) Because it was a royal library, the inventory was skewed toward items of lasting value—literary, scientific, and historical texts. Initially, and at least through the end of the nineteenth century, biblical concerns drove the new field of Assyriology. Sensational was the discovery of a myth of a Deluge in accord in several details with the story of Noah's Flood (Genesis 6–8); some of the Laws of Hammurabi (discovered 1902) paralleled nearly word for word portions of the legal texts in Exodus

20–22; and so on. This era peaked with the “Babel and Bible” controversy, when in a public lecture (also 1902) before the emperor of Germany, the Assyriologist Friedrich Delitzsch proclaimed that the heart of Christian theology could be read from a Babylonian cylinder seal.

Thereafter secular Assyriology gradually prevailed, and now it is the tens of thousands of mundane ephemeral documents—business records, personal letters, property transfers—uncovered over a century and a half of excavation that command the attention of most specialists. From these small clay tablets, which survived because they were imperishable so long as they did not get wet or were not crushed, detailed pictures of two millennia and more of civilizations can be reconstructed.

Hieroglyphs

Alongside the wealth of Mesopotamian materials, the yield of the next most important decipherment, of Egyptian hieroglyphs, seems downright paltry: carvings and paintings on monumental edifices and tombs, which reflect the concerns of their aristocratic patrons (mighty deeds and eternal salvation, basically), and such papyrus documents as were sufficiently highly valued to be immured in watertight tombs with their owners (intellectual property, again largely religious, but not much that was quotidian). The principal name here is Jean-François Champollion, from Grenoble, France, probably building on an insight of the Englishman Thomas Young. The Rosetta Stone alone did not suffice. The only king whose name is preserved in its hieroglyphic portion is Ptolemy, and though it was identifiable because it was enclosed in an oval cartouche, not until Cleopatra's name was found on an obelisk that had been taken to England was it possible to match up signs with sounds. But Champollion's true insights were the recognition that the hieroglyphs did in fact record sounds—were not mystical symbols—and that the clue to the ancient Egyptian language was the modern Coptic language still used in the liturgy of Egyptian Christians. His results were first published in 1822.

Again it was not until the turn of the twentieth century that the decipherment of Egyptian could really pay off for historians, when the American James Henry Breasted methodically explored the Nile Valley, copying, translating, and publishing every historical inscription he could find. But boasts of “mighty deeds” are not all that useful to historians, who appreciate greater detail and welcome opposing points of view. Despite a generation’s head start, knowledge of Egyptian political history still lags behind that of the many lands that used cuneiform, even though the native texts can be supplemented by annals in, primarily, Akkadian and Hittite.

Eastern Mediterranean Scripts

A twentieth-century decipherment whose importance to historians is perhaps on the level of the Parthian/Sasanian is that of the “Hittite” hieroglyphs (actually they record the related Luvian language) used in Anatolia for the millennium or so after 1500 BCE. After fifty years of false starts, it was put on a sound footing by I. J. Gelb and many others beginning in 1931.

Simultaneously a consonantal script akin to the familiar Phoenician, but written like Mesopotamian cuneiform by impressing wedges into clay, which had been discovered in 1929 at ancient Ugarit on the Syrian coast, was deciphered by three scholars working independently. The corpus to date (excavations continue) amounts to only a little over 1,000 tablets, but among them are diplomatic materials that illuminate conditions in the fourteenth century BCE in the Levant; of significantly greater interest are a number of texts that, like some of the early Mesopotamian materials, bear directly on the Bible. The Ugaritic language is nearly a direct ancestor of Hebrew, and the Canaanite gods and religious practices invoked and described—not to mention the poetic styles—correspond closely to many biblical passages that had previously been obscure.

The most recent decipherment of materials pertaining directly to Western civilization was that of Linear B, used on clay tablets at several sites on southern and western Aegean lands. Such tablets were first found at Knossos, Crete, beginning around 1900,

and subsequently at Mycenae and other mainland locations dating to the fifteenth century BCE. An obstacle to the decipherment was the assumption that they had to represent the language of a pre-Greek people; after much preliminary work, in 1952 Michael Ventris had the insight that the language of Linear B was not Etruscan-like, or anything even less well known, but an early form of Greek. Translation of the available materials proved disappointing: they are nothing but economic documents—probably nothing else was ever written down in the script, since the extensive and elaborately painted palace walls are devoid of inscriptions—and the main importance of the decipherment was to demonstrate the presence of Greeks in the region centuries earlier than previously assumed. (In the early 1870s, George Smith and Moriz Schmidt had deciphered the Cypriote syllabary, in which Greek was written on Cyprus about

THE CREATION

the same time the Greek alphabet was being devised: from the eighth century BCE. Materials are meager; one inscription apparently dating from centuries earlier suggests a connection with Linear B.)

The latest decipherment of all, finalized by Ignacio Adiego in the early 1990s, is of the alphabet of the long-known language called Carian, which was found both in Caria in southern Anatolia and throughout Egypt, where Carian mercenaries left graffiti during the second half of the first millennium BCE. Other Anatolian languages, written in alphabets very similar to the Greek alphabet, were known to be later relatives of Hittite and Luvian, but Carian did not seem to fit that pattern—so long as the letters were read as if they stood for the same sounds as Greek letters. Building on the insight of the British Egyptologist John Ray—that Carian spellings of names in Egyptian graffiti probably were to be read as the

corresponding names in the Egyptian versions—Adiego assigned different readings than the Greek to the letters and found that Carian was yet another Indo-European Anatolian language.

South and Inner Asia Scripts

Turning to the East, only three Asian scripts had been so thoroughly lost as to need decipherment. The first two, the Brahmi that is ancestral to a vast range of scripts in South and Southeast Asia, contemporary with India's King Ashoka in the mid-third century BCE, and its slightly earlier predecessor the Kharoshthi, succumbed to James Prinsep in 1837 and 1838 respectively. Brahmi opened up Ashoka's own decrees, which commended Buddhist principles to readers of a variety of Prakrits (early colloquial Indo-Aryan languages; it would not be usual to write Sanskrit for several centuries), and established the starting point for the immense variety of Indian inscriptive scripts (the later forms of which could still be read by the pandits anyway). Kharoshthi was devised for the Gandhari language in north-western India. But both scripts spread along the Silk Road, in both mundane texts and texts providing insight into the development of Buddhism; Brahmi came to be used for some Iranian languages, as well as the defunct Indo-European language family Tocharian.

The other Asian decipherment, of the Turkish or Orkhon runes by Vilhelm Thomsen in 1893, revealed a handful of inscriptions attesting to the presence of Turkic speakers in Mongolia in the eighth century CE, but little more. (The key to the script was an accompanying Chinese paraphrase.)

Scripts from Elsewhere

An important decipherment brings us to the only writing system created in the Western Hemisphere in antiquity: the Maya glyphs of ninth-century CE Mesoamerica (a number of similar-looking graphic complexes of earlier date are known, but they are understood little or not at all). The principal names

 The Book of knowing the evolutions of Rā

 *sekḥer*  *Āpep*  *tcheṭtu*  *Neb-er-tcher*  *tcheṭ-f*
 [and] of over-throwing Āpep. The words of Neb-er-tcher. He says:—

are Yuri Knorosov and Floyd Lounsbury, Soviet and American, who published their results in 1952 and 1973 respectively. Maya monuments commemorate key dates in the lives of rulers of cities; what can so far be interpreted of them has shed light on chronology and ritual. Details continue to be worked out.

A few scripts can be read while their languages remain obscure: the Etruscan of ancient Italy, the Meroitic south of Egypt, the most ancient Iberian in Spain. There are three scripts with corpora large enough that decipherment remains a possibility, but with no texts likely to provide more than minimal economic data: Linear A of the ancient Aegean,

Proto-Elamite of Iran, and the Harappan script of the Indus Valley. Greater potential is offered by the variety of Mesoamerican scripts. But there is little hope that such ill-attested graphic systems as the Phaistos Disk (from Crete) or *rongorongo* (Easter Island) will ever be read—if they are even ways of writing language.

Secondary-Products Revolution

The term *secondary-products revolution* grew out of the focus, from the 1960s to the 1980s, on whether innovations in farming practices arose in response to ecological opportunities and growing population densities, or whether growing social complexity and centralization made such innovations possible. Anthropological theorists in the twenty-first century take a balanced view to encompass both perspectives.

The most fundamental transformation in human conditions in the last ten thousand years was undoubtedly the beginning of farming, termed the “Neolithic Revolution” by the archaeologist Vere Gordon Childe (1892–1957). In several parts of the world, the cultivation of plants permitted unprecedented aggregations of population and the emergence of village communities. The most rapid development took place in the Fertile Crescent of western Asia, the arc of mountains running parallel to the eastern end of the Mediterranean and enclosing the basin drained by the Tigris and Euphrates rivers, which saw the emergence of urban life around 4000 BCE. This latter event, which Childe termed the “Urban Revolution,” was the second decisive turning point in human history and took place as a consequence of the growing scale of interconnections and concentration of resources.

While farming began with the cultivation of cereals and pulses (legumes), the rapid sequence of developments that followed was intimately associated with the keeping of domestic livestock. At first, domesticated animals (sheep, goat, cattle, and pigs) were kept simply as a captive supply of meat. Only later was their potential as draft animals and as

suppliers of products such as milk and meat explored and utilized. Early varieties of sheep, for instance, had hairy coats with only a small amount of wool, while primitive breeds of cattle would have yielded only small amounts of milk. By the time of the first urban communities, however, not only were cattle used for pulling wagons and plows, but new species such as the donkey had been domesticated as pack animals for moving supplies. Soon other species of animals joined the list, including horses and camels for transport, complementing the movement of goods by boats—some of which were now equipped with sails. New types of crop came into cultivation, notably tree crops such as olives, dates, and grapes, which could produce liquid commodities such as oil or sugar-rich liquids suitable for fermentation, paralleling the large-scale use of cow’s and sheep’s milk for ghee (clarified butter) and cheese. Moreover woolly breeds of sheep were in existence, supporting a textile industry that provided one of the major exports of the first cities. It is clear that just as human relationships had grown more complex and diverse, so had the human relationship with crops and livestock, with the domestication of new species and an appreciation not just of the calorific value of plants and animals but of their role as providers of secondary products. The patterns of consumption and technology that arose from these relationships (including alcohol, the plow, horses, wheels, and the wearing of woolen clothes) gave a distinctive character to the societies in which they were present, including the first literate civilizations, and had a major impact on the rest of the world. To signal this transformation in the nature of farming, and in particular the effects that the introduction of these innovations had on neighboring areas such

as Europe and the steppe belt (and, ultimately, even China and the Americas), a third “revolutionary” label in the style of Gordon Childe came into use: the secondary-products revolution of the Western Old World.

It is necessary in this inquiry to raise the question of cause and effect. Did innovations in farming practice arise spontaneously, or at least in response to ecological opportunities and growing population densities, and then make possible a growing scale of trade and more complex social arrangements? Or should the causal arrow be reversed, with growing social complexity and centralization making possible experimentation and the exploitation of innovations? Anthropological theorists of successive generations have given different answers, with the ecological emphasis of the 1960s to 1980s (during which time the term *secondary-products revolution* was formulated) giving way to viewpoints stressing social factors and human agency. A balanced view would encompass both perspectives, including on the one hand ecological possibilities and constraints, on the other the cultural dimension of consumption patterns and economic factors of capital formation and the scale of production. In reality there would have been complex interactions between the two, in a co-evolution of material and social relationships.

We may begin with the distinctive ecology of the region. It is no accident that this area, the meeting point of Africa and Eurasia, between the Mediterranean and the Indian Ocean, should so consistently have produced innovations in material and indeed spiritual life. Its diversity of habitats included highlands and lowlands, forests and deserts, steppes and inland seas, whose contrasts both supported distinctive floras and faunas and promoted specialization and exchange. Its long history of mixed farming encouraged experimentation and the emergence of distinctive local specialties. Recent evidence suggests that milk-products were in use by the sixth millennium BCE, perhaps as early as the use of pottery (which would have been important in making use of it), and a similar time depth may be implied for the emergence of woolly breeds of sheep in western Iran.

Cattle may have been used for treading grain or even to draw simple threshing sledges. Use of wild olives, grapes, and dates may be equally old in the areas where they grow naturally.

Nevertheless there is a perceptible horizon of change associated with the emergence of the first cities in the fourth millennium BCE. It is in this context that we may first observe the use of donkeys as pack animals and the employment of pairs of draft oxen to pull threshing sledges, plows, and solid-wheeled wagons, as well as the keeping of large numbers of wool-bearing sheep and dairy cattle. Some of these activities are reflected in the earliest uses of writing, in the form of pictographic symbols on clay tablets, recording the delivery of commodities at Mesopotamian temple centers. It seems likely that this new scale of production was instrumental in applying what had previously been small-scale regional specialties on an industrial scale to produce commodities, some of which were used as exports, and that these patterns of production and consumption were propagated throughout the region and beyond, stimulating further adaptations and experiments—for instance in the first use of the horse and the camel. From this viewpoint, there is a striking analogy (as Childe perceived) with the Industrial Revolution in eighteenth-century England and its accompanying agricultural revolution. It is in this context—as the agrarian dimension of the “Urban Revolution”—that the secondary-products revolution is best interpreted.

Senghor, Léopold

(1906–2001)

AFRICAN POLITICIAN

Léopold Sédar Senghor was a twentieth-century African poet and politician who lived in both Senegal and France. His work, which blended French, U.S., Caribbean, and African ideas during a time of historic change, helped shape African politics, literature, and the intellectual movement known as “Negritude.”

The African poet, politician, and intellectual Léopold Sédar Senghor was born in Joal, Senegal, as the fifth child of Basile Diogoye Senghor and Gnylane Bakhoun. According to family legend, at the moment of his birth he was possessed by a great spirit that had previously dwelled in a large baobab tree. The tree cracked and fell to the ground the moment he was born. Thus, people believed the spirit had found a new host. His family always referred to him by his birth name, “Sédar,” and he was seemingly destined for greatness. His first seven years were spent among the Serer, a matrilineal (tracing descent through the mother’s line) clan, and he grew up with his mother. His childhood presented him with the problem of competing family claims: those of his mother, his uncle, and his father. He quickly learned to recognize what was appropriate to each and to discipline his own wishes in order to live harmoniously. At age seven he was exposed to his father’s world of international trade and to the missionary and French education systems. He quickly grew to understand old and new Europe and Africa. He learned to balance the demands of multiple responsibilities and loyalties. This balance prepared him for his life as a French politician and an African leader.

His greatest disappointment perhaps fostered his ambition to become a poet and politician. When a

racist priest failed to recommend Senghor for seminary school he was crushed. But when given a second opportunity to attend seminary his response was, “I felt I would not there get the instruments necessary for the liberation of black Africa” (Vaillant 1990, 41). He continued his education in Dakar, Senegal, and in Paris, using poetry and prose as an outlet for his emerging views. His first poetry appeared during the late 1930s at the height of colonial power in Africa. Although he wrote his poetry in French, the language of the colonizer, Senghor gave homage to being black. His poetry celebrated the beauty of African women, the rhythms of the land, and the cultures of Africa, including music, art, poetry, religion, and politics. In his poetry he rejected the subjugated place that European civilization had defined for Africa and Africans. His poetry transcended African, European, and U.S. borders to be widely read and discussed.

As an African living in France, Senghor met Aimé Césaire, who would become his lifelong friend, and this meeting proved another turning point for him. Through Césaire, Senghor was introduced to the Caribbean diaspora in Paris, leading black intellectuals, the Harlem Renaissance, its ideas, music, and literature. Studying the advancement of U.S. blacks gave Senghor hope for Africans. As co-founder of the Negritude movement, Senghor sought to infuse African identity with dignity, pride, and honor. The essential objective of the movement was to define black as beautiful against a backdrop of worldwide racial injustice and discrimination. Using literature and poetry, Negritude attempted to rebuild the validity of African culture and to establish a positive image of black consciousness; Negritude held that a special social quality and humanness exist in blackness.

I have always taken care to put an idea or emotion behind my words. I have made it a habit to be suspicious of the mere music of words. • Léopold Senghor (1906–2001)

In 1948, after reaching success as a poet, publishing numerous books, and co-founding the cultural journal *Présence Africaine*, Senghor returned to Senegal and made the leap to politics fulltime. His life had prepared him well, and he was the consummate politician. He spoke publicly of broad idealistic goals, he was a shrewd deal maker, and he retained a sense of balance necessary for a Christian leader in a Muslim country. He promoted African socialism, accepting the German political philosopher Karl Marx's ideas that people should not be alienated from the products of their labor. He believed that people have natural rights and that people have to remain free agents and creators of culture. However, he rejected Marxism and Communism because he disagreed with the ideas that social complexities universally fit into the concept of class struggles and with Marxism's expressed denial of religion. He played an active role in events that led to the end of the French Empire in West Africa. In 1960 he was elected as the first president of the Independent Republic of Senegal; he served in this position for twenty years before retiring in 1981. As a poet, a co-founder of the Negritude movement, the first black member of the French Academy, and the

first president of independent Senegal, Léopold Sédar Senghor was devoted to bridging cultures.

Sex and Sexuality

Sexual issues have been central to interactions within and between cultures. Religions and law codes from the earliest days sought to define, regulate, or prohibit sexual conduct, as did conquering peoples and states. Some cultures saw sexual relations in terms of rigid categories—homosexual/heterosexual, active/passive—but many cultures around the world had, and sometimes continue to have, more complex systems of gender and sexual classification.

The word *sexuality* is quite new, coming into English and most other Western languages in about 1800. Ancient Greek, medieval Latin, and many other early languages did not have specific words for “sex” or “sexual,” so that they did not define or classify ideas or behaviors in this way. Every human culture, however, has developed norms of sexual behavior, and provided positive consequences for following those norms, along with negative consequences for deviating from them. World history is often told as a story of interactions between cultures, along with the creation of traditions within cultures. Sexual issues have been central in both of these processes.

All world religions, and most indigenous belief systems, regulate sexual conduct and regard sexual behavior as part of a moral system. This began with early sacred texts, such as the Vedic hymns or the Hebrew Scriptures, and continues to today, when issues such as the ordination of openly gay clergy or the proper form of veiling for women divide religious groups more than differences of opinion about theological matters. Many religions set up different standards of sexual behavior for clergy and laypeople, with priests, monks, nuns, and other religious personnel adopting

permanent or temporary chastity as a sign of their holiness. Lay believers may also follow distinctive sexual rules while on religious pilgrimages or other periods of intense spiritual experience.

The earliest written legal codes, and every legal system since, include laws regarding sexual relationships and actions. Hammurabi’s Code of Laws, for example, promulgated in ancient Babylon in about 1750 BCE, sets out which sexual relationships will be considered marriage (and thus produce children who can inherit property), the definition and consequences of adultery and incest, the steps necessary for a divorce, and the consequences of various types of sexual assault. Contemporary national, state, and local law codes do the same.

Encounters between cultures may have taken the form of military campaigns or voyages of trade, but permanent contact often brought laws regulating sexual relationships between groups. The Manchus who conquered China in the seventeenth century and set up the Qing dynasty (1368–1644) prohibited intermarriage between Manchus and Han Chinese. At about the same time in colonial Virginia, according to a state statute of 1691, “English or other white” people were prohibited from marrying anyone who was “negroe, mulatto, or Indian.” Sexual relationships that ignored or defied those laws, particularly between men from the dominant group and women from the conquered or subordinate group, were common in situations of conquest, colonialism, or occupation, but these were generally not regarded as marriage.

Laws and norms regarding marriage and other sexual contacts work to keep groups distinct from one another, and also to preserve hierarchies within cultures, which depend on those in power marrying

people which that society defines as “like themselves.” In Tokugawa Japan (1600–1868), the four legal status groups—samurai, merchant, peasant, burakumin (an outcast minority group who usually did tasks regarded as unclean, such as handling the dead and butchering)—were prohibited from intermarrying, and in many countries of Europe, rulers (at least in theory) lost their claim to the throne if they married commoners. Along with explicit laws, sexual relations between groups have been restricted through the establishment and fostering of traditions and other forms of internalized mechanisms of control. If children are taught very early who is unthinkable as a marriage partner, and unattractive as a sexual partner, the preservation of cultural boundaries will not depend on laws or force alone. Societies sometimes allow elite men to marry or (more often) to have non-marital sexual relationships with non-elite women, though they place various restrictions on the children of those unions. The reverse case is much rarer, because the sexual activities of elite women are the most closely monitored in nearly all societies. Thus socially defined categories of difference such as race, nation, ethnicity, caste, noble status, and social class are maintained by sexual restrictions, for if they are not, those distinctions literally disappear. These restrictions are gendered, with women’s experience different from that of men.

Cultural Variation in Categories and Norms

Sexual issues are thus central to world history, and, like every other facet of human life, sexuality is also historically and culturally variable. Some cultures, including modern Western culture, categorize sexuality primarily in terms of “object choice”—if a person desires or has sexual relations with individuals regarded as of one’s own sex, that person is “homosexual”; if those individuals are of the opposite sex, the person is “heterosexual.” Other cultures categorized sexuality primarily in terms of the role a man took in sexual intercourse. If he inserted something—usually his penis—in another’s bodily orifice, he was taking the

superior “active” role, no matter what the gender of the other person, whose role was viewed as “passive,” and thus inferior.

Both sets of categorizations—homosexual and heterosexual, active and passive—are dichotomous, but many cultures around the world had, and sometimes continue to have, more complex systems of gender and sexual classification. In Australia, Siberia, North America, the Amazon region, Oceania, Central and South Asia, Alaska, and the Sudan, certain individuals were regarded as neither men nor women, or as both men and women, or in some other way as transcending dichotomous gender and sexual classifications. In some cases these individuals appear to have been physically hermaphroditic, either from birth or as the result of castration, though in others their distinctiveness or androgyny was purely cultural. In some cultures such individuals engaged in sexual activities or had permanent or temporary sexual relationships, while in others they did not.

The gender and sexuality of such individuals is complicated and highly variable, but they generally had special ceremonial or religious roles, just as celibate priests, monks, and nuns did and do in Christianity and Buddhism. In south Sulawesi (part of Indonesia), individuals termed *bissu* carried out special rituals thought to enhance and preserve the power and fertility of the rulers, which was conceptualized as “white blood,” a supernatural fluid that flowed in royal bodies. The *bissu* were linked to the androgynous creator deity; they could be women, but were more often men dressed in women’s clothing and performing women’s tasks. In northern India, divine androgyny is replicated in the human world by religious ascetics termed *hijra*, impotent or castrated men dedicated to the goddess Bahuchara Mata; they are regarded as having the power to grant fertility and so perform blessings at marriages and the births of male children. In Polynesian societies, *mahus* perform certain female-identified rituals, do women’s work, and have sex with men, as do the *xanith* in Oman, though this status is temporary and these men eventually marry women.

The best-known example of third-sex categorization is found among certain Native American groups.

We find that the sexual instinct, when disappointed and unappeased, frequently seeks and finds a substitute in religion. • **Richard von Krafft-Ebing (1840–1902)**

Europeans who first encountered them thought they were homosexuals and called them *berdaches*, from an Arabic word for male prostitute. This term can still be found in older scholarly literature, but the preferred term today is “two-spirit people.” Though Europeans focused on their sexuality, two-spirit people (who were usually, though not always, morphologically male) were distinguished from other men more by their clothing, work, and religious roles than their sexual activities. Among many groups two-spirit people are actually thought of as a third gender, so that sexual relations between a two-spirit person and a man may have not been understood as “same-sex” in any case. Two-spirit people were regarded as having both a male and female spirit, so they could mediate between the male and female, as well as the divine and human worlds.

Europeans’ categorization of two-spirit people as homosexual—the description actually used was “sodomite”—highlights a common issue in cultural encounters. Sexual categories and norms within a culture are often so deeply ingrained that they appear

“natural,” the result not of human decisions but of divine mandate or the “laws of nature.” The sexual practices of other cultures are thus made to fit into the existing scheme, and if they cannot, they are judged unnatural or deviant, and may serve as a justification for conquest. “Unnatural” sexual practices became a standard feature of groups other than one’s own, a sign that they were radically “other.” Ancient Athenians told about the Amazons, who lived free of men except for brief encounters for purposes of procreation. Early modern western Europeans saw Turks, especially the sultan and his nobles, as sexually lascivious, lolling around in a harem surrounded by beautiful young women. Nineteenth-century British officials regarded Bengali men, who were thinner and had less body hair than they did, as effeminate.

Premodern Sexuality

Despite the centrality of sexual issues to cultural traditions and encounters between groups, until the 1980s the study of sexuality was often trivialized, and

Artists’ depictions of characters in ancient Greek and Roman mythology have influenced (and been influenced by) perceptions of sexuality in Western culture. **Orazio Gentileschi, *Cupid and Psyche* (1628–1630).** Oil on canvas. Hermitage, St. Petersburg.

seen as a questionable or marginal area of scholarly inquiry. The history of sexuality has since become a booming academic field, but certain areas and periods have received more attention than others.

One of these is ancient Athens, which has traditionally been regarded as a foundation of Western culture and has left many sources, particularly about attitudes toward sexuality among the educated male elite. Plato and Aristotle, the two most important philosophers of ancient Athens, were both suspicious of the power of sexual passion, warning that it distracted men from reason and the search for knowledge. Both men praised a love that was intellectualized and nonsexual, the type of attachment still termed “platonic.” (Neither Plato nor Aristotle was concerned about what sex does to women except as this affects men.) Plato developed a dualistic view of both humans and the world, arguing that the unseen realm of ideas was far superior to the visible material world, and that the human mind or soul was trapped in a material body. This mind/body split was a gendered concept, with men associated more with the mind and women with the body. Women’s bodies were also viewed as more influenced by their sexual and reproductive organs than men’s; Plato described the womb as an “animal” that wandered freely around the body, causing physical and mental problems. (This is why the words *hysteria* and *hysterectomy* both have the same Greek root.) The mind/body split did not originate with Plato, but his acceptance and elaboration of it helped to make this concept an important part of Western philosophy. In Aristotle the mind/body split is reflected in the process of procreation (what he called “generation”), with the male providing the “active principle” and the female simply the “material.”

In classical Athens, a hierarchical sexual and tutorial relationship with an older man—who was most likely married—was part of the expected training in adulthood for adolescent citizens. (Only men could be citizens in Athens.) The older man was the “active,” or penetrating partner, while the younger took the “passive” role. These relations between adolescent and adult men were celebrated in literature and art, in part because the Athenians regarded perfection

as possible only in the male. The perfect body was that of the young male, and perfect love that between an adolescent and an older man, not that between a man and an imperfect woman; this love was supposed to become intellectualized and “platonic” once the adolescent became an adult. How often actual sexual relations approached the ideal in Athens is very difficult to say, as most sources are prescriptive, idealized, or fictional.

In ancient China as well, the idea of a lifelong sexual identity based on the gender of one’s sexual partners was not well established, though at certain times there were male homosexual subcultures in which men participated throughout their lives. The best studied of these is one which developed among imperial officials, intellectuals, and actors in the Song dynasty (960–1279), and male homosexuality was not prohibited until the beginning of the Qing dynasty in 1644.

Sexual activity that could lead to children was clearly a matter of state concern, however. During the Neo-Confucian movement of the Song dynasty, educated officials put great emphasis on the disruptive power of heterosexual attraction, viewing it as so strong that individuals alone could not control it; walls, laws, and strong social sanctions were needed to keep men and women apart and to preserve order within the family. In many parts of China, women of the middle and upper classes were increasingly secluded, and even peasant houses were walled; boys and girls were cheap to hire as servants for tasks that needed to be done outside the walls. Female seclusion was also accomplished through foot-binding, a practice whose origins are obscure and debated, for contemporary official documents rarely discuss it. Foot binding does appear frequently in pornography, however, where the pointed shape that bound feet assumed was compared to lotus blossoms—an erotically charged image—and where the hobbled walk of women with bound feet was described as increasing their sexual prowess by lubricating their genitals. That sexual prowess was to be limited to the men on whom they were dependent, however, for unbound feet were seen as a sign of sexual freedom.

A third well-studied area is early modern colonialism. European accounts of exploration and travel almost always discuss the scanty clothing of indigenous peoples, which was viewed as a sign of their uncontrolled sexuality. Hot climate—which we would probably view as the main influence on clothing choice—was itself regarded as leading to greater sexual drive and lower inhibitions. By the eighteenth century, leading European thinkers such as Adam Smith and David Hume divided the world into three climatic/sexual zones: torrid, temperate, and frigid. (Words that still retain their double climatic/sexual meaning.) They—and many other European writers and statesmen—worried about the effects of tropical climates on the morals as well as the health of soldiers and officials, and devised various schemes to keep Europeans sent to imperial posts from fully “going native,” adopting indigenous dress and mores. They also linked this climatic/sexual schema with the advancement of civilization; in the torrid zones, heat made people lethargic as well as lascivious, whereas a temperate climate (like that of Britain) encouraged productivity and discipline along with sexual restraint and respect for women.

The aspect of “going native” that most concerned colonial authorities was, not surprisingly, engaging in sexual relations with indigenous people; as noted above, colonial powers all regulated such encounters. Indigenous peoples were often feminized, described or portrayed visually as weak and passive in contrast to the virile and masculine conquerors, or they were hypersexualized, regarded as animalistic and voracious (or sometimes both). Racial hierarchies became linked with those of sexual virtue, especially for women, with white women representing purity and nonwhite women lasciviousness. Dispelling such stereotypes was extremely difficult and took great effort; African American women in the early-twentieth-century United States, for example, took great care to hide the sexual and sensual aspects of their lives and emphasize respectability in what the historian Darlene Clark Hine (1998) has called a “culture of dissemblance.”

In the colonial world, both sexual and racial categories were viewed as permanent moral classifications

supported by unchanging religious teachings that determined what was “natural” and what was “unnatural.” Thus same-sex relations were defined as a “crime against nature,” and often tried in church courts, along with other sexual crimes such as adultery or fornication. This link between natural and godly began to lessen in intensity during the eighteenth century, but the importance of “nature” in setting boundaries only intensified.

Modern Sexuality

Many scholars see several developments from the late eighteenth through the early twentieth century as creating a distinctively different “modern” sexuality, though most of this research has focused on the West. The most important of these was a change in the basic paradigm of sexuality from religion to science. Church courts in Europe and the European colonies heard fewer and fewer morals cases, as aberrant sexual desires and actions were no longer viewed as sin, but as “degeneracy” or “perversion.” They were still “unnatural,” but any correction or prevention was to be done by scientifically trained professionals, not pastors or priests. The most important professionals in this new scientific understanding of sexuality were medical doctors. Sex was increasingly regarded as an aspect of health, with doctors determining what was “normal” and “abnormal” based on their understanding of the natural world, not divine sanction.

Western governments sought to promote a healthy society as a way of building up national strength, and anything that detracted from this became a matter of official and often public concern. Masturbation, prostitution, hysteria, pornography, and venereal disease all came to be viewed as sexual issues and health problems, as did what were regarded as more extreme perversions, such as sadism, fetishism, masochism, exhibitionism, nymphomania, and “inversion,” a common nineteenth-century term for same-sex desire. These various sexual disorders were labeled and identified in the German physician and neurologist Richard von Krafft-Ebing’s landmark book *Psychopathia sexualis* (1886), the

first important study in the new medical specialty of sexology.

Masturbation was a matter of concern especially in boys and men; too early or too frequent spilling of sperm might cause them to become weak and feeble, incapable of being good soldiers or workers. A British soldier in Kenya, Robert Baden-Powell, founded the Boy Scouts in 1908 explicitly to teach British boys what he regarded as the right sort of manly virtues and keep them from masturbation, effeminacy, physical weakness, and homosexuality. These were traits he regarded as particularly common among the non-white subjects of the British Empire, and also among the residents of British industrial cities. If they were not counteracted with a vigorous program of physical training and outdoor life, Baden-Powell and numerous other writers, physicians, politicians, and church leaders predicted an inevitable “race degeneration” or even “race suicide.”

Viewing pornography might also lead to weakness, for the new scientific view of sexuality was very concerned with sexual thoughts and desires as well as actions. Pornographic literature had made up a significant share of printed works in Europe since the development of the printing press in the mid-fifteenth century, but was not legally banned because of its sexual content until the mid-nineteenth century with laws such as the Obscene Publications Act passed by the British Parliament in 1857.

Prostitution was also regarded primarily as a threat to men's, and thus the nation's, health. Prostitutes in Europe and the British Empire, or women even suspected of selling sex for money, were required to submit to examinations for venereal disease, though their customers were not, so efforts to control the spread of disease were ineffectual. Prostitution was generally viewed as a necessary evil, a regrettable concession to the strong sexual needs of lower-class men, certainly preferable to masturbation or same-sex relationships. Commentators in this era—the high point of the industrial revolution—often used industrial or mechanical metaphors when talking about sex, describing sexual drives as surging through the body in the same way steam did through engines or

water through pipes. This “hydraulic model” of sex led them to worry about what would happen to men who did not have an outlet; would such “repression” cause them to explode the same way that pipes or engines would if they were blocked?

As they worried about repression and its consequences, sexologists frequently turned their attention to same-sex desire, initially labeling this “inversion,” though eventually the word “homosexuality,” devised in 1869 by the Hungarian jurist K. M. Benkert, became the common term. During the nineteenth century, individuals had often expressed same-sex desire in very passionate terms, but these were generally regarded as “romantic friendships,” expected as a part of growing up and, especially in women, not a sign of deviancy even if they continued throughout an individual's life. The Young Men's Christian Association (YMCA), for example, began in England in 1848 as a Christian men's movement in which young unmarried men were expected to strengthen their character and morality through passionate attachments to one another, a union of souls that would lead to greater love for God. Historians debate whether such friendships should be labeled “homosexual” because this was not yet a category in people's minds, but the medicalization of same-sex desire as a form of sexual deviancy changed attitudes toward them, and intimacy between girls or between boys was increasingly regarded with distrust. By the 1920s, the YMCA's official statements condemned same-sex attraction and espoused a “muscular Christianity,” centered on basketball (invented at a YMCA), swimming, and other sports, and on “normal” heterosexual relationships.

In the early twentieth century, same-sex desire may have been expressed less openly in Europe and North America than it had been earlier, but it also became something that more frequently linked individuals in homosexual subcultures, a matter of identity rather than simply actions. Historians have discovered homosexual subcultures and communities—with special styles of dress, behavior, slang terms, and meeting places—developing among men in European cities as early as the seventeenth

We're all well aware of the male homosexual problem in this country, which is of course minor, but to our certain knowledge there is not one lesbian in England. • **Lord Joseph Chamberlain of England (1836–1914)**

century, but these became more common in the twentieth century, and more often involved women as well as men.

Heterosexuality also became a matter of identity in the early twentieth century, of a permanent “sexual orientation” that eventually became a legal as well as medical term and a central part of modern Western notions of the self. The word “heterosexual” was originally used by sexologists to describe individuals of different sexes who regularly engaged in non-procreative sex simply for fun; it was thus a type of perversion, though a mild one. Increasingly the term came to be used for those who were sexually attracted to the “opposite” sex, with the proper development of this attraction a matter of physical and psychological health. “Normal” heterosexual development was also determined by gender, most famously in the ideas of the Austrian psychiatrist Sigmund Freud (1856–1939). Freud developed the notion that human behavior is shaped to a great extent by unresolved sexual conflicts which begin in infancy; girls suffered primarily from penis envy (the recognition that they are lacking something their brothers have) and boys from an Oedipus complex (the desire to kill their fathers so that they can possess their mothers). Freud’s ideas were vigorously attacked, sometimes by his former associates, but they had a wide impact in fields far beyond psychology such as literature, art, and education.

These scientific and medical studies of sexual attitudes and behavior led to two somewhat contradictory ideas about sexuality. On the one hand, one’s choice of sexual partners or sexual behavior was increasingly regarded as a reflection of a permanent orientation, a “sexual identity” as a homosexual or heterosexual. On the other hand, homosexuality and other types of “deviant” sexuality were defined as physical or psychological illnesses, curable through drugs, surgery, or psychoanalytical analysis. Popular and learned books advised readers about how to achieve a “healthy” sex life, and efforts were made to prevent sexual deviance as well as cure it.

Contradictory ideas and differences of opinion about sexuality and its relation to gender continued

throughout the twentieth century. The first two editions of the American Psychiatric Association’s Diagnostic and Statistical Manual of Mental Disorders (DSM) listed homosexuality as a psychiatric disorder, but in the 1970s it was removed from this list. Some medical researchers investigated a “gay” gene and variations in brain structure, while others criticized their findings as logically and methodologically flawed, shaped by notions of gender that continued to view homosexual men as in some ways feminized. (Most research on homosexuality in the twentieth century, like most medical research in general, focused on men.) At the same time that discrimination on the basis of sexual orientation was prohibited in many areas—largely as a result of the gay rights movement that began in the 1970s—many people (including some gay rights activists) argued that sexual orientation, sexual identity, and perhaps even gender identity were completely socially constructed and could or should be changed, adapted, and blended at will. They asserted that “sexual orientation” and “gender identity” had indeed been part of “modern” ideas about sexuality, but in a postmodern world such concepts were just as outmoded as Plato’s “wandering womb.” They celebrated both historical and contemporary examples of two-spirit people and other forms of nondichotomous gender and sexual categories.

Both “modern” and what might be called “post-modern” sexuality are often seen as Western developments, with groups in other parts of the world regarding these as yet another example of cultural imperialism. In some areas, however, individuals and groups have blended traditional indigenous third-gender categories and more recent forms of homosexual or transsexual identity, asserting that toleration or even celebration of those with distinctive sexuality has roots in their own cultures and is not simply a Western import. At the same time, fundamentalists in many religious traditions, including Christianity, Judaism, Hinduism, and Islam, oppose alternatives to heterosexual marriage, and support the expansion of existing laws regulating sexual relationships. It is clear that sexual issues have not

lost their power as points of conflict both within and among cultures.

Shaka Zulu

(1787–1828) ZULU KING

Shaka Zulu (1787–1828) created an African kingdom that stood as an influential military and economic power at a time when European nations were encroaching on African sovereignty. Shaka's instincts and innovative leadership skills helped to build the mightiest kingdom in sub-Saharan Africa in the early nineteenth century.

King Shaka Zulu increased the Zulu nation to nearly three million subjects and the Zulu kingdom to thousands of square kilometers in the early nineteenth century. He actively participated in the emerging global economy through trade with Europeans, and his military genius changed the art of African warfare.

Shaka was conceived during an affair between his mother, Nandi, who was a Langeni woman, and Senzangakona, chief of a minor Zulu clan. With Shaka's birth eminent, his mother was forced to become Senzangakona's third wife. The union was turbulent, and Nandi and her son were never fully accepted among the Zulu. Nandi was sent back to her people with her son and an infant daughter. Her return to the Langeni forced repayment of the bride price, which brought shame upon Nandi and her children. They were ostracized, and Shaka was frequently teased. When Shaka was fifteen his mother found a home within the Mthethwa confederacy. This confederacy was formed early in the eighteenth century when the chiefs of several small Nguni clans living in the region between the Thukela (Tugela) and Phongolo (Pongola) rivers (now in KwaZulu-Natal), joined forces under Chief Dingiswayo. It was here that Shaka grew into a strong, self-confident leader.

At the age of twenty-three he was drafted by Chief Dingiswayo into the Mthethwa's best regiment. In the military Shaka found his passion and place in life. He quickly developed into a consummate military strategist. In developing his war strategy he designed new types of weapons, as well as improved fighting tactics. He replaced the long-handled throwing spear with a short-handled, broad blade stabbing assegai. He increased the length of the rawhide shield to fully cover a warrior's body. He implemented an attack formation that allowed his army to advance on an enemy from the middle while simultaneously flanking them to attack from multiple sides. The enhanced shields enabled warriors to block the throwing spears of their opponents and get close enough to stab them. Shaka insisted on conditioning; he trained with his men until they could run barefoot 80 kilometers a day. This gave his army advantages in range and speed of attack. He also introduced the concept of unlimited war: annihilation of enemies to prevent reprisal. Previously warfare consisted of ritualistic displays of fierceness, bravery, and then providing forgiveness to the enemy upon defeat. Shaka instituted an aggressive battle style and insisted on complete submission or genocide upon victory.

Shaka was an innovative leader. He formed age-specific regiments that lived in permanent military settlements and remained on duty for years. Girls of marriageable age were formed into female regiments in these towns. These women provided support and agricultural labor. When a regiment had served its time or was particularly brave and victorious they were retired from service and allowed to marry girls from the female regiment. Shaka himself never married. He

Strike an enemy once and for all. Let him cease to exist as a tribe or he will fly in your throat again. • **Shaka Zulu (c. 1787–1828)**

In this 1824 portrait of Shaka Zulu, drawn from life, he stands with the long throwing assegai and the heavy shield.

refused to produce an heir that might one day challenge him for power. When not fighting, the regiments hunted elephants and hippopotamus for Shaka's ivory trade with the Portuguese at Delagoa Bay. Shaka also traded with the English and Dutch, and he granted them land near Natal to promote trade.

As a Mthethwa warrior, Shaka returned to his mother's people and killed those who had tormented him and ostracized his mother when he was young. He assumed control of the Zulu clan with Chief

Dingiswayo's help. Furthermore, when Dingiswayo died in 1818, Shaka became leader of the Mthethwa confederacy. He immediately began to spread his empire; he conquered new lands, created a massive army, and incorporated more and more neighboring polities into the Zulu nation. The wars wrought by Shaka, his generals, and the people he displaced eventually led to massive migration and lethal consequences. The people he attacked were displaced; in their search for new homes they attacked and displaced others. No clan between present-day South Africa and Tanzania was spared this misery. A drought occurring at the same time made cultivation difficult, and people were often displaced before they could reap what they had sown. People wandered from place to place looking for a home. This might be considered the first refugee crisis in southern Africa.

Shaka suffered an emotional breakdown when his mother died in 1827. He went into mourning for a year and insisted his people do likewise, killing thousands for failure to demonstrate adequate sorrow at the queen mother's death. In 1828 Shaka was stabbed to death by his half brother Dingane. But the state he had created resisted European colonialism for fifty years after his death, and the Zulu people remain a recognizable political force in South Africa today.

Shamanism

Shamanism is an ideology and a set of techniques or rituals that deal with communication among spirits. Shamanistic practices are attached to a system of beliefs, and therefore they are always considered in the context of the religion or society in which they are found. The shaman, the person who performs the rituals, often serves as a healer, diviner, clairvoyant, or a possessor of magic or spiritual power.

Shamanism is a distinctive complex of social roles, psychospiritual activities, and religio-ecological ideation embodied in the person of a ritual specialist, called a shaman. The term *shaman* comes from the Siberian Tungus (Evenk) word *aman* via Russian sources. Shamanism has been intensely studied in Eurasia and the Americas, and extends from the Saami (Lapps) of Finland to the Yamana (Yaghan) of Tierra del Fuego at the southern tip of South America. Scholars have also identified shamanism in Aboriginal Australia, Southeast Asia, and Oceania and more sparsely in Africa, where spirit possession and spirit mediumship seem to be more prevalent.

There are many different approaches to the study of shamanism, including anthropology, archaeology, comparative religion, ethnomedicine, history, linguistics, prehistory, psychology, and folklore studies.

History and Distribution

Some scholars claim shamanism displays an ancient heritage discernible in the cave paintings of Paleolithic (foraging) era and hunting cultures found in southern France and northern Spain. For example, the upper Paleolithic Les Trois Frères cave (c. 14,000

BCE) contains the *Sorcerer of Les Trois Frères*, a famous black-painted figure overlooking a gallery of engraved game animals, and interpreted to be a master of animals, a shaman.

Siberia is the locus classicus of shamanism and there is considerable variation from the northwestern Saami (Lapp) shamanism, known only through historical sources first written down in 1180 CE, through to the Turkic Central Asian language group (e.g., Yakut [Sakha], Tuvins, and Khakass), the Mongolian languages (e.g., Mongolian and Buryat), the Tungusic group (e.g., Evenki [Tungus], Even, Manchu), the Paleo-Asiatic (e.g., Chukchi and Koryak) group, and the Eskimo-Aleut group. Shamanism is also found in southern Eurasia in Nepal and India, and throughout Southeast Asia. The Northern and Southern Asian shamanism of Peninsular Malaysia (Bateg, Temoq, Semelai, and Semaq Bri) is remarkably similar to forms found throughout Siberia. Polynesian mythology also amply attests to shamanic themes and cosmological images.

The distribution of shamanism throughout the Americas also suggests not only great antiquity but also Eurasian origins. Shamanism was brought in several waves to the Americas by hunting peoples who crossed the Bering land bridge between Siberia and Alaska. In the far south of Chilean Patagonia artifacts dating between 11,000 and 8000 BCE have been excavated by archaeologists at Fell's Cave. Here too we find shamanism, extinguished by the genocidal wars of the late nineteenth and early twentieth century, among guanaco hunting Ona (Selk'nam) and the marine hunting and littoral foraging Yamana (Yaghan). Farther north in central Chile we find Mapuche shamanism displaying an almost Siberian

Having attracted the disease-spirit into the spirit boat, the Temoq shaman Pak Loong bin Gudam prepares to send the disease-spirit back to its celestial home.

character. Although there is no evidence of cultural continuity between the original settlers circa 10,000 BCE and historically known cultures in this region, the pervasiveness of shamanism throughout the cultures of North and South America certainly indicates a very early introduction. Perhaps the penultimate migration into North America is revealed by linguistic evidence linking the Yeniseian family of languages spoken today only by the Ket of central Siberia with the Na-Dene languages of North America, two culture areas steeped in shamanism. This recent finding further deepens our understanding of the circumpolar

or circumboreal cultural continuum long recognized by scholars.

Shamans and the Shamanic Complex

The shaman is a visionary, healer, singer and poet, ecstatic soul traveler, psychopomp (capable of escorting the soul of the deceased to the domain of the dead), a mediator between his or her social group and the spirit world, a diviner, and a sacrificer. Shamans are specialists in the life and fate of the soul, the travails of their own soul during initiation, and their patient's afflicted soul in a ritual healing performance. These features constitute a complex that frequently lies at the psychospiritual core of a society, and can thus be identified as the religion of many Siberian and circumpolar peoples, as well as the religion of peninsular Malaysia's Temoq, Semelai, and Semaq Bri Orang Asli ("aboriginal") cultures. However, in many other cultures shamanism is just one dimension of a more inclusive religious worldview and in this instance may be more appropriately identified as a belief subsystem as among the Mapuche of Chile and the Uzbeks of Central Asia.

The shaman is a person who is able to break through the planes of ordinary day-to-day life by acquiring a deep and profound knowledge of the supramundane world. Shamanism has been defined as a "technique of ecstasy" involving the magical flight of the shaman's soul to the sky or to the underworld (Eliade 1964, 4ff.). The shaman is empowered to enter into this world through the acquisition of visionary capabilities, most usually during initiation. These powers are renewed and strengthened with every ritual performance directed toward healing, divination, sacrifice, and various other rites important to the welfare of the group. The powers are embodied in the shaman's cosmographic experience and in the control of familiar and guardian spirits who provide knowledge and direction, and protect the shaman's highly labile and vulnerable soul during a visionary rite. The shaman's altered state of consciousness ranges from intense ecstasy as with some Siberian shamans, to quiet reverie as the Malaysian Temoq

shaman contemplates the overpowering beauty of the visionary world. At the age of nine the Lakota holy man Black Elk, during an episode of acute illness, gained his visionary powers by ascending into the cloud-mountain abode of the powerful Grandfathers, who he realized were the “Powers of the World,” the powers of the four directions, the heavens, and the earth below.

Shamanic séances are almost always performed at night, and in many shamanistic societies nighttime is not the absence of daylight, but a qualitatively different type of reality. In almost all societies the shaman is a nocturnal being, a specialist in the existential realities that emerge after nightfall. For the Temoq even seasonality is suspended at night, and the identities that differentiate the diurnal mundane world transform into another dimension at sunset.

Initiation into the shamanic vocation takes many forms throughout the world. In some Siberian societies, the shaman involuntarily experiences a frightening dismemberment by demons or evil spirits. The shaman’s reconstitution into a new, spiritually reborn body empowers the shaman to perform supernormal feats. The death and resurrection theme also occurs in the Americas. In contrast, the Temoq shaman knows he is chosen when he has a waking daylight encounter with the spirit of a beautiful young woman dressed in red. The Temoq mountain journey shaman is then initiated by a master shaman who, during a nighttime ritual performance, places a *cermin*, a “visionary mirror”, into the unawakened third eye of the initiand, thus giving the new shaman’s soul the power to see and visit all the cosmic regions necessary for healing, and for maintaining the fertility and fecundity of the tropical rain forest.

Throughout tropical South America tobacco intoxication and hallucinogens, such as the *Banisteriopsis caapi* plant (ayahuasca), are used to engender visionary experiences. Although only introduced several centuries ago, tobacco is also used by Siberians and some Temoq shamans to induce an altered state of consciousness. The induction of ecstatic trance states by ingesting hallucinogenic mushrooms is also widespread in Siberia.

A ritual assistant daubs a rubber tiger figure, the spirit of which will accompany a Temoq shaman to the edge of world.

Drumming is used throughout Eurasia and in many cultures of the Americas to embrace the suprasensible world of the spirits. In Temoq shamanism intense drumming over several hours, as the author has experienced, induces a soporific state of consciousness, a drowsy state experienced by ritual participants as the temporary loss of their astral body as it travels with the shaman’s celestial entourage.

The *raison d’être* of nearly all shamans is healing. The shaman uses his or her visionary powers to either search out the location of a lost soul or to extract disease-spirits from the body of the afflicted. The retrieval of a lost soul implies that either the shaman or

the shaman's spirit allies journey out into the upper or lower worlds. Although the shaman's expertise is at the center of the therapeutic field, healing is almost always a communal event and often an intense social drama.

Shamans are preeminently singers and poets. Whether ecstatic cries of a Siberian Sakha shaman, the long spirit-journey epics of Malaysian Semaq Bri, Semelai, and Temoq shamans, or the low murmuring of Yamana shamans in Tierra del Fuego, almost all shamans vocally express their experience through singing. In some societies such as the Temoq and the Siona of South America, the song is the primary expression of the shaman's power. Indeed, for the Temoq, the term "song" is a misnomer, for only powerless shamans sing "songs," while powerful shamans give fresh and clear voice to visionary experience. The Temoq shaman's singing is replete with the calls of animal and bird familiar and guardian spirits. A beautiful example is the Tuvan shaman's song in *Shu-De*.

The Shamanic Worldview

Shamanic activity is couched within a cosmological structure that facilitates the movement of the shaman's soul or spirit from the middle world of human society and the natural world to the upper and lower worlds inhabited by ancestors, guardian and familiar spirits, deities, animal masters, the land of the dead, and frequently the soul of a patient. A multi-tiered world, often three-tiered, is integrated by an axis mundi—a vertical structure lying at the center of the world and imaged as a tree, a mountain, a pillar, a rainbow, or even a river that flows from the upper world, through the middle world of day-to-day life, to the lower world of the dead as with the hunting and reindeer-herding Evenki of the Siberian taiga.

In a ritual performance the shamanic cosmos is symbolically represented in the structure and function of the shaman's venue and in the shaman's costume and musical instrument, such as a drum or rattle. This ritual microcosmos, projected to the "center of the world," embodies core symbolic forms that,

variously empowered, enable the shaman to engage spirits and supernatural beings and visit the far-off places necessary for the success of the ritual.

The shaman's costume itself constitutes a religious hierophany and cosmography; it discloses not only a sacred presence but also cosmic symbols and metaphysical itineraries. Properly studied, it reveals the system of shamanism as clearly as do the shamanic myths and techniques. (Eliade 1964, 145)

The Evenki (Tungus) shaman's *kamlanye* performance demonstrates the relation between their shamanic worldview and the structure of the ritual venue. The tepee-shaped tent is either a modified domestic tent or one specially constructed by clan kinsmen several days before the performance. The ordinary tent is used for rites directed at finding lost reindeer or foretelling the future and as a preparatory venue for major rites where the shaman fasts, smokes heavily, and encourages visionary dreams.

Major *kamlanye* performances were held for guiding the soul of a dead person to the underworld, for feeding ancestral souls, and for the expulsion of disease-spirits. The ritual tent, containing a larch sapling positioned next to the hearth and emerging through the smoke hole, is surrounded by a small fenced-off enclosure containing platforms and carvings representing the structure of the world and designed to assist the journey of the shaman's animal-double spirit—his *khargu*—to the lower world. From inside the tent the east-facing shaman sees a double row of wooden knives and bear spears, and wooden images of salmon and pike familiar and guardian spirits. The shaman's drum (made of larch wood) and drumstick are often imaged as the canoe and paddle by which the shaman travels the shamanistic clan river. In front of the tent entrance is the *darpe*, a gallery of fresh larch saplings with roots skyward, and carved shamanic figures representing the upper world. To the west of the tent the *onang* structure, representing the lower world of the dead, constructed from dead fallen timbers, displays carved larch trees with roots facing downward. In the upper world larch trees grow downward from the soil of the sky vault, whereas

they grow upward in the lower world. The larch tree protruding through the smoke vent signifies the world tree integrating the three levels or planes of existence. During a performance the shaman's spirit climbs the cosmic larch tree in his ascent to the upper world.

Similarly, while singing and drumming a Chilean Mapuche *machi* or shaman climbs her *rewe*, a large pole often displaying carvings of her familiar spirits, during a *machitan* or healing rite. Aboriginal shamans in central Australia climb a pole to signify ascent, and in Malaysia the Temoq shaman, traveling the rainbow shadow snake, signifies his ascent by dancing over the patient with a model of the world tree bedecked with miniature birds and fruit. The vision of Black Elk the Lakota shaman also strongly embodied the image of a life-giving world tree intimately connected to the welfare of his people.

Shamanism Today

Siberian shamans were persecuted and imprisoned and thousands died during the Soviet era. Since the establishment of the Russian Federation shamanism has shown a remarkable resurgence along with re-emergent ethnicities in such places as Tuva. A clinic has been opened by shamans in Kyzyl, the capital of the Tuvan Republic, south Russia, where shamanism and Buddhism amicably coexist. Folk groups travel with shamanically inspired repertoires to international venues, and many documentaries have been made on shamanism over the past few years. Native American shamans travel to Mongolia to deepen their calling under the tutelage of Mongolian shamans. In other places shamanism is under pressure not only from missionary activities, but also from globalization, which is seriously threatening the languages and cultures of minority peoples.

In the West, shamanism has captured the imagination of many, and this new form, called neoshamanism, attempts to selectively integrate aspects of indigenous shamanism with a range of concerns from New Age spirituality to transpersonal psychology. Neoshamanism aspires to go beyond modernity by grounding identity within a more inclusive spiritual,

psychological, and ecological vision of personal, social, and planetary well-being.

Sheep and Goats

The first herd animals to be domesticated, originally about 8000 BCE in Anatolia and Iraq, were sheep and goats. They became the focus of entire civilizations, since pastoral people would devote their lives to tending the flocks. The metaphoric significance of both animals in the Bible and Greek myth—Jesus as the Lamb of God; Dionysus fleeing to Egypt as a goat—reflects somewhat their animal natures: sheep as benign, goats as rambunctious.

The ancestor of domestic sheep was the mouflon (*Ovis orientalis*), which may still be found wild in mountainous regions of Sardinia, Cyprus, and other islands in the Mediterranean or near the Atlantic coast. These sheep, however, may well be feral rather than wild varieties, which escaped human control in remote times. Several varieties of sheep, however, have never been domesticated, primarily because they cannot easily be herded. Among these is the American bighorn sheep (*Ovis canadensis*) found in the Rocky Mountains, which, though untamed, provides wool used by the Navajo and other Native American tribes in intricately woven and brightly colored blankets.

Sheep—together with goats (*Capra aegargus*), their close relatives—became the first herd animals to be domesticated, originally in Anatolia and Iraq, by about 8000 BCE. The domestication of sheep was a gradual process that probably grew out of efforts of hunters to manipulate stampeding herds. By the third millennium BCE, captive herds had become common throughout the Near East, central Europe, and western Asia. These animals became the focus of entire

civilizations, since pastoral people would center their entire lives on the task of tending flocks. Tribes would, for example, be inhibited from creating permanent settlements, since it was necessary to move on when vegetation in one area was exhausted.

As human population increased and people were compelled to abandon the lives of hunter-gatherers, a rivalry between herders and agriculturalists became more intense. This rivalry is commemorated in the biblical story of brothers Abel and Cain. Abel was a shepherd and offered a sacrifice of a sheep to Yahweh (God), whereas Cain tilled the soil and offered up fruits and vegetables. When Yahweh looked with favor only on the sacrifice of Abel, Cain became angry and killed his brother (Genesis 4).

Social Organization

One consequence of the domestication of animals for food was that it enabled people to store up considerable amounts of wealth, which led to increased social differentiation. Herds of animals are often mentioned in the Old Testament of the Bible and other books of the ancient world as a measure of riches. The earliest coins, from Lydia in the seventh century BCE, were stamped with pictures of food animals, and their value was measured in livestock.

The Hebrews were a nation of herders, especially of sheep, and important biblical figures, including Abraham, Jacob, Moses, and David, were shepherds. The relationship of a shepherd to his flock provides an important metaphor for benevolent leadership in many biblical passages. A good example is the psalm known today as “The Lord’s Prayer,” which begins:

Yahweh is my shepherd
I lack nothing
In meadows of green grass he lets me lie.
To the waters of repose he leads me. . . . (Ps. 23:1–4,
Jerusalem translation)

The society of the Hebrews, as described in the Bible, did indeed have some organizational resemblance to that of sheep. In both there was generally a single leader, but otherwise membership was comparatively egalitarian. Anthropologists have observed that this

pattern is generally characteristic of semi nomadic herders, in contrast to societies of agriculturalists with their complex gradations of status and power.

The metaphorical importance of sheep continues in the New Testament. On seeing Jesus for the first time, John the Baptist says, “Look, there is the lamb of God that takes away the sins of the world” (John 1:29). In the book of Revelation, “the Lamb” is repeatedly used to refer to Christ.

Like other closely related animals—for example, the dog and the wolf—sheep have constantly been contrasted with goats, which are relatively fierce and independent. The Greek god Dionysus took the form of a goat when fleeing to Egypt during the war between the gods and the titans. The festival

Hubert and Jan Van Eyck, *The Adoration of the Lamb* (detail from the Ghent Altarpiece completed in 1432). Angels, prophets, and popes kneel before the sacrificial lamb, which symbolizes Jesus.

A lamb figures in the deadly rivalry between the biblical Cain and Abel: God favored Abel's sacrifice of a lamb over Cain's offering of grain.

of Dionysus, out of which Greek tragedy emerged, climaxed with the sacrifice of a goat.

But perhaps because of their association with pagan gods of Greece and Egypt, the Judeo-Christian tradition often viewed goats as diabolical. Jesus speaks of separating the sheep from the goats at the Last Judgment (Matthew 25:31-46), a metaphor for the division of the just from the damned. In medieval Europe, Christ was often depicted as a lamb, while the devil was portrayed with the horns of a goat.

Industrial Society

Large forests throughout the Near East and Europe were cut down to provide grass for sheep and other herd animals. Overgrazing drastically reduced the fertility of the soil in the Mediterranean region, contributing to the decline of ancient civilizations such as those of Greece and Mesopotamia. In a similar way, the forests that once covered most of central Spain were later cut down to make way for the prized merino sheep, a breed introduced to the region by Moors in the twelfth century. Rains then washed the topsoil away, doing enormous damage to Spanish agriculture.

Scholars often consider the beginning of farming during Neolithic times and the Industrial Revolution starting around the eighteenth century as the two great revolutionary changes in human society, and sheep played an important role in both changes. Modern animal husbandry began when the English farmer Robert Bakewell (1725–1795), an expert on sheep, developed scientific methods of breeding. This enabled people to produce sheep that would yield greater amounts and varieties of wool. In 1764, the spinning jenny was invented by the Scotsman James Hargreaves (c. 1720–1778). This machine helped people to exploit the wool, in a mechanized textile industry, which provided a model for mass production that was soon extended to many other kinds of manufacturing.

The new technologies created a demand for wool in unprecedented quantities, which, in turn, led to massive changes in the traditional societies of Britain and continental Europe. To clear the land for herding of sheep, many tenant farmers in Britain were forced off their ancestral lands in the late eighteenth and early nineteenth century in what is often known as the “tragedy of the commons.” This, in turn, led to rapid urbanization, as well as increased emigration to the Americas.

Every man can tell how many goats or sheep he possesses, but not how many friends. • **Marcus Tullius Cicero (106 BCE–43 CE)**

A Romantic Image

Shepherding has always been celebrated by poets for the closeness it provides to nature and the opportunity it allows for contemplation. Around the middle of the eighth century BCE, the Greek poet Hesiod told how the Muses had inspired him as he was tending sheep. In early modern times growing urbanization created a nostalgic longing for rural life, and the shepherd became a favorite figure of poetic literature. At the end of the novel *Don Quixote* by the Spaniard Miguel de Cervantes (1547–1616), the dreamy hero, disillusioned with the life of chivalry, decides to become a shepherd. The French queen Marie Antoinette (1755–1793) would dress and act the role of a shepherdess on a bucolic farm where she went to escape the intrigues of the French court. But the idealized image of the shepherd or shepherdess cherished by aristocrats was far from the reality of people who depended on sheep for a living.

As synthetic fabrics have become more widely available, the wool industry has become considerably less significant economically. Nevertheless, sheep became an important part of yet another potential upheaval in

human society in 1996, when a sheep named Dolly (1996–2003) became the first mammal ever to be successfully cloned.

Shinto

The practices of Shinto in Japan developed over centuries, perhaps beginning as early as the fourth century BCE, and became distinctive as influences from Buddhism and Chinese religions spread eastward. A characteristic feature of Shinto, which still pervades contemporary Japanese culture, is *kami*, beings that dwell in heaven or reside on Earth as sacred forces within nature.

Shinto is the name for the religious beliefs and practices that are believed to have developed in Japan prior to the importation of foreign religious traditions from the Asian continent, beginning in the sixth century CE. With rare historical exceptions, the Japanese have not attempted to propagate Shinto outside of Japan, believing that it was the foundation of their cultural heritage and identity. One might conclude that the impact of Shinto in world history has been minor, but this is not the case. Shinto deeply influenced Japan's interactions with other cultures. Moreover, it continues to serve as a major religious and cultural institution in contemporary Japan.

Shinto in the Premodern Period

It is difficult to say with any certainty when Shinto began. Shinto had no founder and no scriptural tradition. Rather, the elements of what eventually became identified as Shinto developed over a period of centuries, perhaps from the fourth century BCE to the sixth century CE. During this period, ritual specialists worshipped spirits called *kami*; Shinto, in fact, literally means the "Way of the *kami*." While "spirit" is one generally accepted English equivalent for *kami*,

the concept of the *kami* defies any simple translation. One eighteenth-century scholar of Shinto offered this explanation:

I do not yet understand the meaning of the term *kami*. Speaking in general, however, it may be said that *kami* signifies, in the first place, the deities of heaven and earth that appear in the ancient records and also the spirits of the shrines where they are worshipped . . . It also includes such objects as birds, beasts, trees, plants, seas, mountains, and so forth. In ancient usage, anything whatsoever which was outside the ordinary, which possessed superior power, or which was awe-inspiring was called *kami*. (Motoori Norinaga, quoted in Tsunoda 1958, 21)

Until the seventh century CE, there was no coherent state in Japan. Instead, various clans controlled their own territories. Historians believe that one of these clan leaders managed to convince other powerful clans of his ability to communicate with the *kami*. Over the course of the fifth and sixth centuries, the hereditary leader of this clan formed alliances with other clans, and Japan's first state, known as Yamato, was born. The leader of the dominant clan became the sovereign of this state and the "emperor" of Japan. That clan's connection with the *kami* meant that Shinto was linked with the new ruling family. Three of the most important Shinto shrines, for example, house the regalia that symbolize imperial rule. The Grand Shrines at Ise, which have been rebuilt every twenty or twenty-one years since the seventh century, are especially important as the primary site for the reverence of the *kami* Amaterasu, the deity of the sun and divine ancestor of the imperial family. It is at the Ise shrines that certain Shinto rituals connected with

the imperial family, such as the enthronement of a new emperor, are usually conducted.

The institutional and doctrinal character of Shinto during this early period lacked coherence. Its rituals and practices were confined mostly to the social and political elites of the clans; the rest of Japanese society had their own forms of worship, which were only absorbed into Shinto in the nineteenth and twentieth centuries. Shinto became more clearly defined in contradistinction to Buddhism, which arrived in Japan in 538. Korean monks from the state of Paekche brought copies of Buddhist sutras with them to Japan, and many of these monks took up residence in Japan as teachers. Unlike Shinto, Buddhism had a founder, scriptural texts, and an exegetical tradition. Japanese elites were fascinated with Buddhism, which far surpassed Shinto in the sophistication of its teachings and practices. The “magic” of Buddhism, as evidenced by some Buddhist monks’ knowledge of medical herbs and healing, also seemed superior to the magic of Shinto. During the sixth century, a rivalry developed between the adherents of Buddhism and Shinto priests, and it was during this period that Shinto began to develop a true institutional identity.

Although Shinto never lost its close association with the imperial court, Buddhism was very nearly given the status of a state religion in 745 CE by Emperor Shomu (701–756; reigned 715–749). In addition, Buddhism began to appeal more to the general populace during the eleventh century, as less esoteric, more faith-based schools of Buddhism were introduced. For the most part, Shinto leaders ignored commoner worshippers.

Ryobu Shinto

During Japan’s classical and medieval periods (seventh through sixteenth centuries), there were two important developments in Shinto. The first was the emergence, beginning in the ninth century, of an esoteric strain called Ryobu Shinto, a syncretization of esoteric Buddhism and Shinto that equated particular Shinto deities with particular Buddhist deities. In this effort, the Shinto deities were viewed as incarnations of Buddhist gods, so that the latter took precedence over the former. In Ryobu Shinto, Shinto’s doctrinal void was filled with Buddhist teachings. Ryobu Shinto was a dominant presence in the world of doctrinal Shinto until the fifteenth century.

A Shinto shrine in Japan. Deep connections to the Japanese imperial institution survive to this day, helping Shinto to preserve its authority and majesty.

Yoshida Shinto

A Shinto priest, Yoshida Kanetomo (1435–1511), was dissatisfied with Ryobu Shinto because of its theological emphasis on Buddhism. He reversed Ryobu Shinto's syncretistic hierarchy and introduced Neo-Confucian values and teachings into Shinto. The result was called Yoshida Shinto. Although there were other Buddhist-Shinto blendings prior to the seventeenth century, Yoshida Shinto gradually became associated with the imperial court and Yoshida priests became the court's ritual specialists.

Shinto and Modern Japan

During the early modern period, roughly 1600 to 1870, scholars and intellectuals who wanted to purge Shinto of all foreign influences created a new field of Shinto scholarship. These nativist scholars (Japanese: *kokugakusha*) argued that Shinto must be purified of its long-standing ties to Buddhism, since the latter was a foreign creed. Yoshida Shinto's emphasis on Neo-Confucianism was similarly problematic because Neo-Confucianism was an intellectual import from China. The nativists believed that their mission was to eliminate foreign doctrinal contaminants from Shinto and to replace them with authentically Japanese teachings and values. They argued that these teachings could be found after a careful and thorough examination of Japan's classical literature, especially works composed

in the period from the eighth to thirteenth centuries. According to the nativists, once Shinto was properly purified, it could become the basis for asserting a truly unique Japanese culture, which they believed was the only way to rectify the problems of their society. At the same time, the nativists of the early modern period believed that Shinto's lack of articulated teachings was one of its unique and valuable features. There was no need to govern the behavior of the Japanese people, they argued, because they were already blessed by the *kami* with the internal capacity to self-regulate. Another aspect of Shinto that the nativists called attention to, and that continues to be important in contemporary Shinto, is Shinto's the reverence for nature. Scenes of natural beauty, such as mountains, rock formations, and waterfalls, are believed to harbor their own *kami*. To commemorate the presence of the *kami*, a small shrine is erected, symbolized by a *torii*, a gate-like structure composed of two support beams and a crossbeam.

In 1868, when samurai political domination came to an end and the emperor was, in theory, restored to actual power, Shinto was given renewed cultural and political power. Shinto priests advocated that the new government be modeled on the one that had existed before the advent of warrior rule in 1192. Although the effort to resurrect the imperial government of the classical period was abandoned in favor of the creation of a government similar to those of the European powers, the services of Shinto priests were

retained by government officials in the movement to establish a state religion. Japanese intellectuals argued that the material and technological successes of the Europeans were rooted, in part, in the strength of their religious values. The Japanese, they believed, needed to identify their own values and foreground them if they were to transform Japan into a strong nation like those of the West. After much debate, chiefly with the Buddhists, the Shinto priests succeeded in the creation and adoption of State Shinto. Thus, Shinto had an instrumental part in the emergence of Japan's modern state.

During the 1930s and 1940s, supporters of State Shinto were vocal supporters of the view that it was Japan's destiny to dominate the rest of Asia. When the tide turned against Japan in World War II, "special attack brigades" were formed, the most famous of which were the suicide pilots who flew their planes into enemy ships. Since the hope was that these pilots could reverse Japan's military decline, the Japanese called them the *kamikaze*, the "wind of the *kami*" in a deliberate invocation of a typhoon that had arrived,

apparently in answer to the prayers of Shinto priests, and destroyed the boats of an invading Mongol army in the thirteenth century. Just as the *kami* had saved Japan from the Mongols, it was hoped that they would save it from the Allies.

In the postwar period, one shrine has generated controversy beyond Japan's borders. Yasukuni Shrine in Tokyo was originally built at the end of the nineteenth century to commemorate the souls of those who had fought on behalf of the imperial court in the overthrow of the samurai government in 1868. Later, it became the site for the veneration of soldiers and sailors who had died in subsequent wars, such as the Sino-Japanese War (1894–1895), the Russo-Japanese War (1904–1905), and World War I. In the postwar period, the ranks of those who had died in World War II were included in that number. Government leaders, including the prime minister, have paid official visits to the shrine. This has sparked outrage in both North and South Korea and in the People's Republic of China over what the populations in those countries feel is a show of respect for the dead of an unjust and

Small shrines to commemorate the presence of a *kami* are symbolized by a *torii*, a gate-like structure composed of two support beams and a crossbeam. Photo by Mark McNally.

aggressive war, and a sign that Japanese claims of remorse for the war are not genuine.

Contemporary Shinto

The leaders of the postwar Allied Occupation of Japan (1945–1952) insisted that the Japanese abolish State Shinto. Although the imperial institution was allowed to endure, Shinto itself settled into two major forms. The first, a successor to State Shinto, is a set of practices surrounding the emperor and the imperial court, but purged of prewar ideology. The other developed out of traditions not directly associated with the imperial court. These were the benign practices performed by many Japanese people as a way to mark important events, such as the milestone years of childhood, the coming of age for young adults, and especially weddings.

Shinto manifests itself in the lives of ordinary people in other ways as well. Purification rituals are a common occurrence in contemporary Japan. Metaphors of purity and defilement are central to Shinto. Many Japanese will hire Shinto priests to purify people, places, and objects by driving out evil spirits. A building site is normally cleansed after construction and before it is open to the public. In order to invoke the protection of the *kami*, many Japanese purchase talismans (*omamori*) from shrines for such things as academic success and successful conceptions. On the eve of their high school or university entrance exams, students compose notes inscribed with their wishes for academic success and tie them to tree branches at Shinto shrines. Throughout the year, in all parts of Japan, people participate in festivals that are usually organized around local Shinto shrines.

It is perhaps not inaccurate to characterize Shinto as a religion of practitioners but not believers. While there are some worshippers who observe Shinto exclusively, most Japanese people observe both Buddhist and Shinto practices, exhibiting what some Japanese scholars describe as a kind of psychological “cohabitation.” For example, it is not uncommon for families to make offerings in their home at both

a Shinto “*kami* shelf” (*kamidana*) and at a Buddhist altar (*butsudan*). The latter is especially important for the veneration of ancestors and recently deceased family members.

Shinto and World History

Although Shinto is not generally considered to be one of the world’s great religions, it has had an impact on world history. It has had its moments of infamy, serving as the pretext for war and invasion. During the 1570s, the war leader Toyotomi Hideyoshi (1536–1598) rose to become the most powerful samurai in Japan, earning the title of imperial regent. In a letter to the Portuguese viceroy in Goa, he cited Japan’s special place in the world by invoking Shinto: “Ours is the land of the Gods [*kami*], and God is mind. This God is spoken of by Buddhism in India, Confucianism in China, and Shinto in Japan. To know Shinto is to know Buddhism as well as Confucianism” (quoted in Tsunoda 1958, 317). Hideyoshi made it clear that his rule was with the consent of the *kami* and the emperor, who himself was viewed as a living *kami*. Empowered with the sanction of Shinto, Hideyoshi ordered the invasion of Korea in 1592, with the eventual goal of subjugating China. Hideyoshi’s death put an end to his plans for conquest, but not before Japanese forces had wreaked considerable havoc in Korea. In Japan, however, he was deified and subsequently worshipped as a Shinto *kami*.

As mentioned earlier, Shinto was also invoked in Japan’s rise to militarism and imperialism in the 1930s. The unique “Japanese soul” (*Yamato damashii*) bespoke innate Japanese superiority and fostered an attitude of contempt for other, lesser peoples.

But Shinto was also instrumental in the emergence of the modern state in a more positive sense, supporting a sense of place and a sense of community. Shinto’s deep connections to the Japanese imperial institution survive to this day, helping it to preserve its authority and majesty. Even without a coherent doctrinal tradition, Shinto has functioned as the

foundation of Japan's cultural identity for more than a millennium.

Sikhism is an eclectic faith combining the teachings of Hinduism and other traditions first laid down by its founder, Guru Nanak (1469–1539?), in the Punjab region of India. Sikhs have migrated to many parts of the world and set up large communities; they stress respect for other faiths, emphasize a sense of social duty, and give great importance to the equality of all human beings.

Sikhism is a religion that developed in the Punjab area of the Indian subcontinent in the fifteenth century CE. The founder of the religion was Guru Nanak, who was born in 1469 CE in Talwandi. Guru Nanak was originally a Hindu, but drew upon a range of religious influences in creating his distinctive spiritual message. In his early years he earned his living by keeping financial records, but was attracted to the religious life, and made a series of journeys to religious sites that were significant to both Muslims and Hindus. It seems that he traveled to Varanasi (Benares), to the very south of India, and also to Mecca. After this long period of pilgrimage, Guru Nanak moved to the village of Kartarpur in the Punjab where he gathered around himself a community of disciples. Toward the end of his life, Guru Nanak selected a man named Lehna to be his successor. From then onward, Lehna became known as Guru Angad.

In his teachings Guru Nanak laid the religious foundations of Sikhism, but his spiritual successors amplified the teachings. After Guru Angad there were eight other Sikh gurus, culminating in Guru Gobind Singh, who died in 1708 CE. The teachings of some of the Sikh gurus, along with those of several Hindu and Muslim teachers, were ultimately gathered

together into the definitive scripture, the *Guru Granth Sahib*. The names and dates of the ten Sikh gurus are: Guru Nanak (1469–1539?); Guru Angad (1504–1552); Guru Amar Das (1479–1574); Guru Ram Das (1534–1581); Guru Arjun (1563–1606); Guru Har-gobind (1595–1644); Guru Har Rai (1630–1661); Guru Hari Krishen (1656–1664); Guru Tegh Bahadur (1621?–1675); Guru Gobind Singh (1666–1708). It was decided by Guru Gobind Singh that he would be the last person who was guru, and that from then onward, the scripture of the Sikhs, the *Guru Granth Sahib*, would become the guru.

Religious Beliefs

Sikhism is a monotheistic religion that lays emphasis upon the relationship of the individual with God. The Sikh scripture emphasizes the influence of God in creating an ethical unity or the Punjabi *hukam* in the universe. The goal of human beings should be to try to live according to this ethical principle, while at the same time not being egoistic or focused on the self. If the individual tries diligently to adhere to this way of life, then with the grace of God, it is possible to attain salvation. Sikhs may also use a form of meditation involving the repetition of the name of God, to assist in achieving salvation. The state of salvation is sometimes described by the Punjabi term *sahaj*, which indicates the merging of the individual with the divine.

In a Sikh community, worship is normally focused upon a *gurdwara*. This is a place of communal worship, in which is kept a copy of the *Guru Granth Sahib*. This scripture is regarded with great reverence by the Sikhs, as it is considered to be one of the principal

A Sikh family crosses a bridge over the Thames. Founded in India, Sikhism is now a world religion, with Sikhs living in many nations.

ways in which God reveals his teachings to humanity. The holy book is kept on a pedestal at one end of a large prayer room, in which when services are being held, men sit on one side and women on the other. Worship at the *gurdwara* may consist of readings from the *Guru Granth Sahib*, the singing of hymns accompanied by music, and also spiritual talks.

After the worship, there is often a communal meal or *langar*. This social custom was instituted by the Sikh gurus to emphasize the equality of all people. In the India of the time, there were a number of prohibitions about food that related to the caste which a person occupied. The Sikh gurus felt that these were inappropriate, and the *langar* was developed to stress the absence of social divisions among Sikhs. Guru Nanak was opposed to extravagant forms of religious ritual, and this is reflected in the relative simplicity of Sikh worship. Sikhism does not particularly attempt to convert people to its faith. While Sikhs are very proud of their own religion, they also show respect for other faiths.

Historical Development

Sikhism developed at a period of conflict in northern India, exacerbated by the geographical position of the Punjab on the natural invasion route from the north into India. The historical period covered by

the Sikh gurus saw intermittent conflict between the developing Sikh community and the Muslim invaders of India. The Sikhs felt, to some extent, the need to defend their community militarily in order to survive. But relations with the Mughal Empire were at times very friendly. Guru Amar Das, for example, was a contemporary of the Mughal emperor Akbar (ruled 1556–1605 CE), and it seems likely that the two men did in fact meet, under very amicable circumstances. Guru Arjan, on the other hand, possibly because of political conflict, alienated the emperor Jahangir (ruled 1605–1627) and was subsequently executed. The emperor Aurangzeb (ruled 1659–1707) instituted a period of stricter observance of Islamic views. There was conflict with the Sikhs, and the ninth guru, Tegh Bahadur, was ultimately executed. His son, Guru Gobind Singh, became leader of the Sikh community, and introduced changes that were to have long-term consequences for Sikhs. Besides establishing the Sikh scripture as Guru, he instituted the *khalsa*, or community of people who had been formally accepted as Sikhs. Members of the *khalsa* tend to be recognized by five characteristics: they do not cut their hair; they wear a comb to keep it in order; and they wear a sword, a steel bangle on the wrist, and a pair of shorts beneath their outer garment. These customs have given Sikhs a sense of coherence as a community.

When all efforts to restore peace prove / useless and no words avail, / Lawful is the flash of steel, / It is right to draw the sword. • **Guru Gobind Singh (1666–1708)**

Influence of Sikhism

Although there was some continuing conflict between Sikhs and Muslims, the Sikh community managed to sustain its sense of identity. In recent times, Sikhs have migrated to many parts of the world and set up large and successful communities, for example in Canada and in London. Sikhism has emphasized a number of principles that are of value to the world faith community. It has stressed a respect for other faiths; it has emphasized a sense of social duty, and given great importance to the equality of all human beings.

Silk Roads

The Silk Roads were an elaborate and ever-changing network of overland trade routes that linked China, India, and western Eurasia for many thousands of years. Their existence ensured that the history of Eurasia had an underlying coherence, despite the significant cultural differences between its regions.

A late nineteenth-century German geographer, Ferdinand von Richthofen, first used the label *Silk Roads* in honor of the shimmering lightweight fabric that was their most famous and exotic commodity. But the Silk Roads carried much more than silk—they also carried languages, technologies, artistic styles, goods, and even diseases between the great agrarian civilizations of Eurasia. Scholars began to appreciate the importance of the Silk Roads in the late nineteenth century, during the international contest known as the Great Game, which pitted Russia and Great Britain against each other for influence in Central Africa. To Russian and British officials, Central Africa seemed a remote backwater, ripe for colonization because of its strategic position. But as European and Russian soldiers, diplomats, and scholars began to scout out the lands of Central Africa, they learned that flourishing trade routes had once crisscrossed the region, supported by ancient cities, some of which had long vanished under desert sands. In the twentieth century, several generations of archaeologists, historians, and linguists undertook the daunting task of recreating the lost world of these ancient trade routes.

For world historians, long-distance exchange routes are of great importance. William H. McNeill has argued that the exchange of ideas and technologies

between different regions may be one of the most important of all engines of change in world history. As the most durable links between major population centers in the largest landmass on earth, the Silk Roads count as one of the most important of all long-distance exchange routes in human history. Study of the Silk Roads has made it apparent that Eurasian history consisted of more than the separate histories of Mesopotamia, Egypt, Europe, India, Southeast Asia, and China. On the contrary, for several thousand years, the Silk Roads ensured that these regions were never entirely disconnected. As Marshall Hodgson noted as early as the 1950s, “historical life, from early times at least till two or three centuries ago, was continuous across the Afro-Eurasian zone of civilization; that zone was ultimately indivisible” (Hodgson 1993, 17).

Geography and Early History of the Silk Roads

The distinctive way in which the Silk Roads linked the different regions of Eurasia is explained by the large-scale geography of the Eurasian landmass. Eurasia consists of two very different regions. Around its western, southern and eastern rims, in what we can call Outer Eurasia, there lie several subcontinental peninsulas, partially separated from one another by seas and mountain chains. Because these regions are southerly and well watered, agriculture flourished there, so it was there, in Mesopotamia, India, and China, that Eurasia’s first agricultural civilizations appeared from about five thousand years ago. Links between the different parts of Outer Eurasia were tenuous enough that each region developed its own

A rubbing of text from a tomb in China shows Persian (Farsi), Arabic, and Chinese, three languages that traveled along the Silk Roads.

cultural and technological styles. Further north, in regions dominated during the twentieth century by the Soviet Union (which we can call Inner Eurasia), climates were harsher and more arid. Few practiced agriculture here, except in parts of modern Ukraine and Central Africa, and there were few towns and cities until recent centuries. This huge zone, largely devoid of agriculture, helped separate the major agrarian civilizations.

Yet the absence of agriculture did not mean that Inner Eurasia was a historical backwater. From about 4000 BCE pastoralist lifeways, based on the exploitation of domesticated animals, began to spread in the steppes of Inner Eurasia. By 2000 BCE pastoralists were grazing their livestock from Hungary to the borders of Mongolia, and in the first millennium BCE pastoralism also spread into Mongolia and parts of Manchuria. Moving with their herds and spending much of their time on horseback, pastoralists were much more mobile than farmers and ranged over large

areas. But it was difficult for them to grow and store crops, so most traded with farming communities at the edge of the steppes, exchanging livestock products for agricultural produce and urban manufactures. In this way, pastoralists gradually created far-reaching systems of exchange that operated in relays from Siberia to India and from China to the Mediterranean. With the spread of pastoralism, Inner Eurasia, which had once seemed a barrier to communications across Eurasia, became a new channel of communication. How extensive these links could be is suggested by the spread of Indo-European languages from somewhere north of the Black Sea to Xinjiang (northwestern China), India, Mesopotamia, and Europe, borne almost certainly by the spread of pastoralist communities speaking closely related languages.

Early evidence of trade along the Silk Roads comes from the so-called Oxus civilization, a cluster of fortified farming and trading cities built about 4,000 years ago on the borders between modern Afghanistan, Turkmenistan, and Uzbekistan. Here, archaeologists have found Chinese silks, goods from India and Mesopotamia, and pottery and ornaments from the steppes. The archaeological evidence suggests a pattern of cooperation between urban merchants and steppe pastoralists, a pattern that survived into modern times. Eventually, there emerged sophisticated systems of trade, organized in caravans sometimes with hundreds of individuals, often financed by urban merchants, and supplied with urban manufactures and regional specialties. At least by the first millennium BCE, and perhaps much earlier, caravans could stop at special rest stations known as caravansaries established by local rulers or merchants and sometimes fortified. Caravansaries offered accommodation, repair workshops, and food, as well as information about what lay ahead. Between stops, caravans often traveled through lands controlled by pastoralists, who would provide protection (at a price), as well as guides, and who traded goods such as hides and horses. Without the consent and cooperation of the pastoralists through whose lands they passed, the Silk Roads could not have functioned at all.

The Silk Roads were not the only exchange networks linking the different agrarian regions of

Eurasia. As early as the third millennium BCE, sea routes helped link the civilizations of Mesopotamia and the Indus valley, and in the first millennium CE trade through the southern seas became increasingly important. Nevertheless, for several millennia, the Silk Roads were the most extensive of all trans-Eurasian exchange systems.

The Silk Roads at Their Height

The Silk Roads grew in importance late in the first millennium BCE, when major agrarian empires began muscling in on them from the south, west, and east. Around 529 BCE, Cyrus I, the founder of the Persian Achaemenid dynasty, invaded the lands of pastoralists known as the Massagetae in modern Turkmenistan. Though Cyrus was killed by the Massagetaen queen, Tomyris, his successors established a loose hegemony over much of modern Turkmenistan and Uzbekistan. Two centuries later, Alexander III of Macedon (Alexander the Great) conquered much of Central Africa, and a century after that, the Chinese emperor Han Wudi sent an envoy, Zhang Qian, into the same region. Zhang Qian embarked on an epic fourteen-year journey, much of which he spent as a captive of the pastoralist Xiongnu. He returned with enthusiastic reports of the wealth of Central Africa, but the emperor was particularly impressed by accounts of the magnificent “blood-sweating” horses of Fergana. Han Wudi sent an army westwards to claim his share of the wealth traveling through Central Africa, and ever since Chinese rulers have taken a keen interest in Xinjiang and Central Africa. Like Cyrus and Alexander, Wudi found he would have to fight regional pastoralist leaders for control of the Silk Roads, and he embarked on a contest for control of Xinjiang that the Chinese were to continue, with fluctuating success, until the early 1900s.

Further west, Rome’s great rival, Parthia (c. 238 BCE–c. 226 CE), which was founded by a dynasty of pastoralists, controlled the western end of the Silk Roads. Parthian rulers protected their monopoly on trade to the Mediterranean, and tried hard to prevent Roman traders from taking alternative routes through India. Though none of the great powers permanently

A textile merchant in the Silk Roads city of Samarqand displays silk, cotton, wool, and carpets (early twentieth century).

loosened the grip of regional pastoralists on the Silk Roads, their intervention did stimulate trade. Indeed, so abundant is the evidence for exchanges in the final century of the first millennium BCE that many scholars have argued that this is when the Silk Roads really flourished for the first time. At the battle of Carrhae (modern-day Haran, in southeastern Turkey), in 53 BCE, Parthian armies flew silken banners from China; from around 100 BCE, China began to import horses from Fergana; in the Xiongnu tombs of Noin-Ula in the north of modern Mongolia, archaeologists have found textiles from Central Africa and Syria; and in the steppe tombs of Pazyryk, in the Altay mountains, they have found Persian carpets.

In the second and third centuries of the common era, Central Africa was dominated by the Kushan Empire, which had been founded in approximately 45 CE by a dynasty of pastoralist rulers originally from eastern Xinjiang. The Kushan Empire traded with Inner Eurasian pastoralists and with the Mediterranean world, India, and China; all these regions influenced Kushan culture. For example, Kushan religious traditions included deities from the steppes, as well as Zoroastrian, Greek, and Buddhist deities, but they were also influenced by Jainism and Vaishnavism, while other religious traditions, including Nestorian Christianity and elements of Confucianism, were also present within the empire. Exchanges along the Silk Roads were particularly vigorous in the sixth and seventh centuries, when the Chinese Tang dynasty

(618–907 CE) was unusually open to influences from the West. These influences included musical and artistic styles from Persia, and Buddhism, which reached China from India, traveling with merchant caravans.

Trade was also stimulated by the creation of large and powerful steppe empires dominated by dynasties of Turkic origin, all of which were interested in long-distance trade. In the late sixth century, a Turkic leader, Ishtemi (reigned 552–c. 576), working closely with Sogdian merchants from the trading cities of Central Africa, sent trade delegations as far as Constantinople, and we know of at least one return mission, led by a Byzantine official called Zemarkhos, that probably traveled to Ishtemi's capital in Xinjiang.

The following account, written by the Muslim geographer al-Muqaddasi in about 985, gives some idea of the variety of commodities carried along the Silk Roads in the first millennium:

from Tirmidh, soap and asafoetida [a strong-smelling resinous herb]; from Bukhara, soft fabrics, prayer carpets, woven fabrics for covering the floors of inns, copper lamps, Tabari tissues, horse girths (which are woven in places of detention), Ushmuni fabrics [from the Egyptian town of Ushmunayn], grease, sheepskins, oil for anointing the head; . . . from

Khorezmia, sables, miniver [a white fur], ermines, and the fur of steppe foxes, martens, foxes, beavers, spotted hares, and goats; also wax, arrows, birch bark, high fur caps, fish glue, fish teeth [perhaps a reference to walrus tusks, which were carved into knife handles or ground up and used as medicine], castoreum [obtained from beavers and used as a perfume or medicine], amber, prepared horse hides, honey, hazel nuts, falcons, swords, armour, khalanj wood, Slavonic slaves, sheep and cattle. All these came from Bulghar, but Khorezmia exported also grapes, many raisins, almond pastry, sesame, fabrics of striped cloth, carpets, blanket cloth, satin for royal gifts, coverings of mulham fabric, locks, Aranj fabrics [probably cottons], bows which only the strongest could bend, rakhbin (a kind of cheese), yeast, fish, boats (the latter also exported from Tirmidh). From Samarqand is exported silver-coloured fabrics (sim-gun) and Samarqandi stuffs, large copper vessels, artistic goblets, tents, stirrups, bridle-heads, and straps; . . . from Shash [modern Tashkent], high saddles of horse hide, quivers, tents, hides (imported from the Turks and tanned), cloaks, praying carpets, leather capes, linseed, fine bows, needles of poor quality, cotton for export to the Turks, and scissors; from Samarqand again, satin which is exported to the Turks, and red fabrics known by the name of mumarjal, Sinizi cloth [from the Fars region, though originally the flax

for them came from Egypt], many silks and silken fabrics, hazel and other nuts; from Farghana and Isfijab, Turkish slaves, white fabrics, arms, swords, copper, iron; from Taraz (Talas) goatskins . . . (Barthold 1977, 235–236)

Traffic along the Silk Roads was never more vigorous than in the thirteenth century, when the Mongol Empire controlled almost the entire network from China to Mesopotamia. Like most pastoralists, Mongol rulers valued and supported long-distance trade. Karakorum, the Mongol capital, though far from any of the great agrarian centers of Eurasia, became briefly one of the most cosmopolitan cities in Eurasia; here all of Eurasia's great religions jostled each other, including Buddhism, Nestorian Christianity, Islam, Daoism, and Confucianism, as well as the still-vigorous religious traditions of the steppes. Italian merchant houses published special travel guides for merchants traveling to Mongolia and China; Chinese officials acted as advisers to the Mongol rulers of Persia; and Muslim merchants managed the tax systems of China.

The cultural and technological integration of Eurasia through the Silk Roads helps explain the technological and commercial precocity that gave Eurasians such a devastating advantage when they encountered peoples of the Americas and the Pacific. The technologies of pastoralism, including horse riding, as well as Chinese inventions such as the compass and gunpowder, which had traveled to Europe along the Silk Roads, gave colonists from Eurasia such a decided advantage.

But as William H. McNeill has shown, epidemiological exchanges through the Silk Roads were equally significant. The Black Death almost certainly traveled from China through the Silk Roads, but similar epidemiological exchanges between different agrarian civilizations had occurred several times before this. For example, the plagues that devastated parts of the Roman Empire in the second and third centuries CE may also have arrived via the Silk Roads. As McNeill has argued, these epidemiological exchanges help explain why, when peoples from Eurasia eventually

encountered peoples from the Americas and the Pacific, they enjoyed epidemiological as well as technological and military advantages: in the more populous areas of the Americas populations may have declined by up to 90 percent after the arrival of Eurasian diseases such as smallpox.

The Silk Roads in Decline

After the decline of the Mongol Empire in the fourteenth century, other trade routes began to assume greater importance, and the relative importance of the Silk Roads declined. More maneuverable ships plied new sea routes that spanned the globe; guns and cannon challenged the military power of pastoralists; and in the nineteenth century, steam engines began to displace horses and camels in the steppes. Meanwhile, as agricultural populations began to settle the lands that became Muscovy and Russia, trade was diverted north and west. Today, Central Africa is still a region of vigorous inter-Eurasian trade, but the Silk Roads count as just one of many different systems of exchange that link Eurasia and the globe into a single system. This makes it all too easy to forget that for perhaps four thousand years they were the main link between the forest dwellers of Siberia, the pastoralists of the steppes, and the agrarian civilizations of China, India, Persia, and the Mediterranean. Because of the Silk Roads, Indo-European languages are spoken from Ireland to India, Buddhism is practiced from Sri Lanka to Japan, and inventions such as gunpowder, printing, and the compass became part of a shared Eurasian heritage. The Silk Roads gave Eurasia a unified history that helps explain the dominant role of Eurasian societies in world history in recent millennia.

Silver

Silver has affected human culture and history since ancient times. Silver coinage increased trade, affected the type of trade goods, changed societal structures, and led to war. The 1500s saw new mining and refining techniques and the discovery of silver lodes in the New World, which affected cultures there. Since 1900, industrial uses have superseded its use as currency.

Silver is a rare metallic element widely distributed in the Earth's crust and usually found mingled with lead, copper, and zinc ores. In pure form it is soft and easily scratched, so alloys are used for jewelry and tableware. Pure silver is the best conductor of electricity and heat among all metals. That gives it widespread uses in electronics, so much so that modern industrial demand for silver exceeds annual rates of production. Historically its principal uses were for coinage, ornament, and tableware.

Impact on Ancient Civilization

Coinage was by far the most important for human affairs at large. The earliest coins were made in the kingdom of Lydia (680–547 BCE, located in modern Turkey) from a mixture of gold and silver. Later, during the Persian Empire (550–330 BCE), Persian kings coined pure gold. A single Persian gold coin paid a mercenary soldier for an entire year. But such coins were far too valuable to be of much use in everyday buying and selling. In fact the Persian kings made such little use of them that gold coins accumulated in the royal treasury until Alexander III of Macedon (Alexander the Great, 356–323 BCE) destroyed their empire and disbursed their treasure.

Silver is more common than gold, so coins of silver were cheaper; and in the course of the sixth century BCE Greek cities began to issue them in smaller sizes than the Persian gold coins. This made everyday buying and selling far easier than when barter had prevailed, requiring both buyer and seller to have goods of equal value readily available before a deal could be made. The result was to make market transactions far more pervasive, and thus bring rural populations into the marketplace regularly instead of subsisting on what they could raise locally.

Greek farmers soon discovered that by using their fields to raise wine and olive oil instead of grain, they could sell these products to merchants who shipped them abroad and returned with grain, timber, and other raw materials. This had profound consequences for Greek society and civilization. First, the terms of trade favored Greek oil and wine producers. They received more grain than they could raise at home for their exports, because special skills and a favorable climate were needed for grapevines and olive trees to flourish, while grain was raised everywhere and did best in richer soils than those of Greece. Second, grape and olive harvests came late in the fall and needed little or no attention in summer. This allowed landowning Greek farmers to take full part in war and other public enterprises. Indeed they became the ideal type of citizen and soldier, thus mobilizing a far larger proportion of the entire population for public action than was possible elsewhere.

The result was a richer, more leisured, and more formidable society than could otherwise have been sustained in the rocky and not very fertile land of Greece. Their success in repelling a formidable Persian invasion (480–479 BCE) under King Xerxes I was

proof of what they could achieve. By chance, just as silver coins by then underpinned the Greek economy, newly discovered veins of silver at Laurium in Attica allowed the Athenians to enlarge their fleet of warships on the eve of Xerxes' attack. These silver mines were worked by slaves and owned by the state. In 483 BCE, an Athenian politician named Themistocles persuaded the Athenian assembly to use their new wealth in silver to enlarge the navy. As a result, by the time the Persians appeared the Athenian fleet had grown from seventy to two hundred triremes. Without the silver of Laurium, that could not have happened. And without the new Athenian triremes, the Greeks could not have defeated the Persians at the Battle of Salamis, depriving Xerxes' army of adequate supplies from home and requiring him to withdraw most of his soldiers from Greece and leave only a relatively small army behind that met defeat on land the next year.

Rowing in triremes required nothing more than a strong back. That gave the unpropertied Athenian citizens, who could not afford to equip themselves with armor, an important new role in war. Athenian democracy emerged in succeeding decades as a result.

Moreover, the fleet permitted military mobilization of all Athenian citizens, making their city a great power in Greece for about a century and supporting an age of literary and artistic achievement unequalled before or after. In view of silver's role in sustaining Athenian greatness, it might best be called a silver age, but calling it a golden age is conventional and unlikely to change.

The meteoric career of Alexander the Great (reigned 336–323 BCE), king of Macedon and conqueror of the Persian Empire, spread Greek influence eastward to the borders of India. Among their other novelties, Alexander and his successors expanded the scope of market relations throughout western Asia and Egypt by founding cities and introducing small silver coins, without turning rent-paying peasants into citizens or soldiers. Wealth increased and long-distance trade both in the Mediterranean Sea and the Indian Ocean swelled on the strength of enhanced buying and selling.

Greece languished, however, partly because deforestation and subsequent erosion damaged farmland, partly because so many emigrants left to seek their fortunes in the new cities of western Asia and Egypt,

and mainly because Greece faced increasing competition when the production of wine and olive oil for export spread to southern Italy and then to Spain. This westward expansion of olive groves and grapevines sustained a large-scale circulation of goods of common consumption within the Mediterranean coastlands that reached its climax under the Roman Empire between 30 BCE and 165 CE.

As before, oil and wine producers enjoyed advantageous terms of trade while grain and raw material suppliers were disadvantaged; however, both prospered until a disease disaster between 165 and 180 CE killed about a third of the population. Another lethal epidemic raged from 251 to 266 CE; by then barbarian invasions from the north and civil disorders had spread destruction far and wide, frequently followed by famine.

The population of the Roman Empire partially recovered by the time of Constantine (reigned 312–337 CE); although the western provinces remained impoverished, cities remained little more than empty shells, and subsistence farming made tax collection clumsy and inefficient. Classical Mediterranean urban society and its silver-based currency had disappeared from the west but survived on a diminished scale in the east, allowing the East Roman or Byzantine Empire to survive for more than a thousand years.

Impact from 1500 to 1800

When cities and trade revived in western Europe, silver currency alongside gold again facilitated exchanges. Silver production became significant in Europe when German miners learned how to dig and drain deeper shafts in search of silver and other metals. But exactly when and how their skills developed went unrecorded until 1556 when a German named Georg Bauer, better known as Georgius Agricola, published the book *De re metallica* that describes their methods in full detail. How silver was mined elsewhere also remained unrecorded, though we know silver production assumed a large scale in Japan by the sixteenth century.

Historic illustration of a member of the Navajo tribe wearing a silver belt. New York Public Library.

Old World silver mining was soon dwarfed by what happened in the Americas when Spaniards discovered rich ores in Mexico and more especially a “silver mountain” at Potosí in the high Andes of Bolivia (1546). They conscripted many thousands of indigenous people in Mexico and in Bolivia to dig the newly discovered silver, and they also introduced an efficient new way of refining the ore by heating it with mercury.

Silver jewelry, designed and executed by Arthur J. and G. C. Gaskin in 1914, inlaid with a variety of opals, pearls, crystals, and turquoise. New York Public Library.

The output from Potosí and Mexico was so prodigious that shipments of silver to Spain and China upset prevailing prices everywhere, inaugurating a worldwide inflation that peaked in the 1630s. Thereafter, Potosí's richest lodes petered out and simultaneous shortages of mercury reduced silver output drastically. By then silver from the New World had quadrupled prices in Spain and raised them almost as much across Europe and Asia, all the way to China, where disruptive effects were magnified by the fact that the Ming dynasty shifted its currency from copper to silver coinage.

Rather abrupt climate change, nicknamed "the Little Ice Age," peaked in the 1640s and contributed to the economic crunch that inflation and the

subsequent diminution of supplies of silver created. Ninety years of inflation caused landowners and governments to raise rents and taxes everywhere; those who paid them were sure that wicked greed and corruption were rampant as never before. No one understood how more silver coins purchasing almost the same amount of goods allowed sellers to ask and receive more money for the same old thing. And wherever colder, wetter weather diminished crops, rising food prices inflicted real suffering on millions of people. Sudden reduction of silver output in the 1630s had a no less disruptive impact on commercial affairs.

Under these circumstances, religious and political upheavals became widespread. In Europe, Germany's Thirty Years War (1618–1648) was particularly devastating, but civil war in England (1640–1660) and the Fronde in France (1648–1653) also reflected social strains exacerbated by the price fluctuations that American silver, and the sudden diminution of its flow, provoked. Further east, the Ottoman Empire saw a sultan deposed and succeeded by a ten-year-old boy in 1648, followed by near anarchy until 1656. And in China, the Ming dynasty collapsed in 1644 after years of disorder, to be succeeded by the Manchus' Qing dynasty.

China had become a magnet for the world's silver since it was almost the only commodity Europeans, Japanese, and other foreigners could offer to the Chinese in return for silk, porcelain, and other manufactures. It came directly across the Pacific from Mexico to the Philippines and thence to China, as well as via Europe and the Indian Ocean. The Chinese needed to import silver for their currency since production in China itself (mainly in Yunnan) was insufficient. Scholarly controversy still prevails about how critical interruptions in silver supply may have been in provoking the disorders that overthrew the Ming.

Impact since the 1800s

In succeeding centuries, human affairs were not affected so drastically by silver, since supply and demand for that metal became more evenly balanced.

Silver lodes were exhausted, new ones discovered, and its worldwide use slowly increased. Discovery of the Comstock lode in the U.S. state of Nevada in 1859 was like a lesser and more local Potosí, achieving peak production in 1876. For the rest of the nineteenth century, westerners sought to make silver as good as gold for backing American paper dollars. An economic depression in 1893 made the question central to the presidential election of 1896. But the Democratic candidate, William Jennings Bryan, met defeat after denouncing bankers and their friends for crucifying the country “on a cross of gold” and ran a second time in 1900 only to fail again.

That is the last time silver played a prominent role in politics. In the twenty-first century, its industrial and electronic uses outweigh its use for coinage, for modern “silver” coins are silver only in color and made of cheaper metals. The high Andes still produce more silver ore than anywhere else, but Potosí and the Comstock lode are both totally exhausted. Jewelry, candlesticks, forks, spoons, and other familiar items made of silver continue to be melted down

from time to time and recast in newer styles much as before.

Sima Qian

(c. 145–86 BCE)

CHINESE HISTORIAN OF THE HAN DYNASTY

Sima Qian was the first true historian of China. Although others had compiled earlier historical works, mostly in the form of state chronicles or collections of documents and anecdotes, Sima Qian was the first to write a history of China under his own name. The history he produced in the second century BCE—the *Shiji* (*Records of the Grand Historian*)—provided a model for Chinese historians over the next two thousand years.

The *Shiji* (*Records of the Grand Historian*) was the first official history of China authored by one person, Sima Qian, a court historian of the Han dynasty (206 BCE–220 CE). Most of what we know of Sima Qian's life comes from the last chapter of the *Shiji*, which included his autobiography. There we learn that his father, Sima Tan (d. 110 BCE), was a court astrologer to Emperor Wu (reigned 141–87 BCE). As a young man Sima Qian received a classical education and traveled extensively. At the age of twenty he entered government service as a “gentleman of the palace.” Eventually he inherited his father's office of grand astrologer, a position that combined record keeping with the interpretation of natural phenomena and, equally important, gave him access to the imperial library. His father had started a history, and on his deathbed Sima Tan begged his son to continue his efforts. It is not clear how much Sima Tan had actually written, but Sima Qian went on to complete a comprehensive history of China from its legendary beginnings to his own age.

Besides the *Shiji*, Sima Qian's surviving works include a letter to a friend, Ren An, explaining his actions in what is known as the Li Ling affair. Li was a

capable Han general who had led his army deep into the territory of the Xiongnu nomads on China's northwestern frontier. When his forces were surrounded and defeated he had surrendered, provoking Emperor Wu's wrath. Officials at court who had been praising Li only days before now joined in a chorus of condemnation. Sima spoke up for the general and in doing so offended the emperor and was sentenced to castration. Where other men might have chosen suicide rather than mutilation, Sima reluctantly accepted his humiliating punishment so that he could have time to finish his history.

The *Shiji* comprises 130 chapters: twelve basic annals, which recount earlier dynasties and the reigns of individual emperors in the Han; ten chronological tables correlating major events in the feudal states (both autonomous states in the pre-imperial Zhou dynasty and also semi-independent kingdoms within the Han empire); eight treatises on ritual, music, pitch-pipes, the calendar, astronomy, state sacrifices, waterways, and economics; thirty chapters on various hereditary houses (these were devoted to the feudal lords), and seventy “arrayed traditions.” The arrayed traditions are biographical chapters that often combine the life stories of two or three individuals who knew each other or were in some way similar (such as the philosophers Laozi and Han Feizi). The traditions also include group biographies of assassins, scholars, harsh officials, wandering knights, imperial favorites, diviners, and money makers. In addition, six of them describe various nomadic peoples that lived on China's borders.

Sima Qian ended most chapters with a brief appraisal prefaced by the phrase “The Grand Astrologer remarks.” Otherwise, his interpretive comments are

Though bitter, good medicine cures illness. Though it may hurt, loyal criticism will have beneficial effects. • **Sima Qian** (c. 145–86 BCE)

sparse and, at least for his accounts of early history, he borrowed extensively from already existing records. This has led some to view Sima Qian, for better or worse, as a cut-and-paste historian. Yet the unusual structure of his history allowed him considerable leeway to shape the perceptions of his readers through his editing. For instance, Confucius, who was by no means a feudal lord, got his own chapter in the hereditary house section—a sign of the importance Sima Qian attached to him, and unflattering details about particular individuals can show up when they are mentioned in the biographies of others.

There is a tremendous amount of information contained within the *Shiji*, but the fragmented, overlapping structure of the tome means that details about pivotal figures may be scattered over several chapters. It is a book that cannot be mastered one time through, and in its original form—written on thousands of bamboo slips—it would have been even more difficult to handle. Nevertheless, Sima Qian's literary style and bold innovations inspired later historians. His work became the first of the “Standard Histories,” of which there are now twenty-six, although unlike the *Shiji* the later histories limited their focus to a single dynasty, and many enjoyed official sponsorship. Yet they continued Sima Qian's basic format of annals, treatises, and arrayed traditions (the hereditary houses were omitted as the empire became more centralized).

From our perspective today, the *Shiji* is a significant cultural expression of the political trend in Sima

Qian's time toward consolidation. Just as the Han emperors had worked to bring “all under heaven” under their control, so Sima tried to bring together all of China's history, geography, and culture within a single work. Sima himself believed that, having met failure and disgrace in his own life, he was writing primarily for future generations. In this ambition he certainly succeeded.

Slave Trades

The trading of slaves had its origins when agricultural societies increasingly needed to defend lands and borders; it proliferated as growing empires expanded their own. Transatlantic slave trade, with its infamous Middle Passage, ensnared roughly 11 million people between 1443 and 1870; historians caution that using only slave-ship records to account for such numbers leaves out millions who perished in forced marches to factories on the African coast.

Slave trades began with the onset of agricultural societies. As hunter-gatherers also became farmers, they settled down at least temporarily, defending their lands from both nomads and other farmers. The ensuing wars yielded prisoners, who then became convenient forced labor for the victors. More wars in an area meant more available slaves, who then could be sold to others in exchange for food, copper, and later money. This exchange was particularly true in Mesopotamia, India after the Aryan migrations, China under the Zhou dynasty (1045–256 BCE), and the Greek city-states. For example, in Sumeria in southern Mesopotamia this labor was used to perform the constant maintenance of irrigation canals as well as to build ziggurat temples. Egypt and Harappa (in the Indus River valley of modern Pakistan) had far fewer slaves until outsiders attacked, and their societies became more warlike than before in response. China and India had fewer slaves than Mesopotamia and Greece. Strong central governments that reserved slavery largely to themselves and that were blessed with more peasant farmers than they needed condemned fewer individuals to being outright chattel (an item of tangible property except real estate

and things connected with real property) in eastern Asia.

Empires transmitted both slavery and slave trades. The Mediterranean world witnessed upsurges in the number of people in bondage with the imperial expansion of Athens, of Alexander III of Macedon (Alexander the Great), and then of Rome. Prisoners whose families could not afford or arrange a ransom were quickly sold and resold. Slave trades came to Gaul, in what is now western Europe, and Britain. Thanks to senatorial policy, the center of Mediterranean slave trading moved from the island of Rhodes to the smaller yet more accessible island of Delos to the even more convenient Rome itself. as the historian Keith R. Bradley has noted, “piracy and kidnapping contributed to Delos’s ability, according to [the Greek geographer] Strabo, to dispose of tens of thousands of slaves in a single day, its volume of traffic being specifically geared toward Roman demand” (Bradley 1989, 22). On a smaller scale, in the Americas slavery and the slave trades blossomed long before Columbus. Mayan city-states enslaved defeated opponents, keeping some of them ultimately as objects to sacrifice to the gods. In the Andean region the Mochica celebrated the actual moment of enslavement during war through exquisite pottery art.

While the Americas remained isolated from intercontinental contacts and thus from long-distance slave trading, Africa became a center of large-scale human trafficking with the domestication of the camel during the first millennium CE and the spread of Islam into the lands south of the Sahara Desert after 800 CE. The trans-Saharan caravan trade mainly exported gold for basic commodities such as salt, but it also spread faith in Allah as well as toting captive women and children for sale as domestics and concubines in Arab caliphates (the offices or dominions of successors of Muhammad as temporal and spiritual heads of Islam). This trans-Saharan slave trade was small in comparison to the later transatlantic one, but it unfortunately accustomed western Africans to the idea of exporting human beings centuries before the Portuguese came to their coasts.

Monotheistic religions intensified and justified slave trades, particularly in Africa and around the boundaries between Christian and Muslim states such as in Iberia (modern-day Spain and Portugal). Muslims, in particular, viewed slavery as a prelude to conversion, but actual conversion did not preclude enslavement. Enslavement was just too profitable and necessary for converts to be allowed to go free. Accordingly, crusades and jihads (holy wars) dehumanized the enemy, making them fit to be treated as disposable property.

When the Roman Empire itself declined in western Europe after 200 CE, slavery and the slave trades also declined and disappeared there. Feudalism and serfdom emerged eventually to provide cheap and reliable sources of agricultural labor for governing elites. Serfdom supported local subsistence farming, whereas slavery persisted in and around the Levant (countries bordering on the eastern Mediterranean) to support large-scale cultivation for export. What the historian Philip Curtin has called “the plantation complex” (Curtin 1990, ix) began with Arab sugar planters in Mesopotamia using African and local prisoners of war about 800 CE. This complex gradually spread westward to the Levant, then to Cyprus, then to Crete, then to Sicily, then to Atlantic islands such as the Canaries, then to Sao Thome, and then finally to Brazil. Slave trades followed this westward trek, supplying the foreign, coerced workers for lucrative sugar plantations that needed vast numbers of

A late-nineteenth-century lithograph illustration titled, "In the slave market at Cairo."

workers to cultivate many acres in order to be profitable. Yet, slave trades also developed from south to north and from west to east. As noted, sub-Saharan Africa supplied Islamic caliphates with concubines and domestics, whether in Cordoba, Jerusalem, Mogadishu, or eventually Delhi. Yet, these slaves were a mere fraction of the global number of slaves. When Europeans thought of slaves before the fall of Constantinople (modern Istanbul, Turkey) in 1453, they usually thought of the Slavic peoples caught in the wars between Muslims, Mongols, and Russians around the Black Sea. In fact, the word *slave* comes from this medieval association of forced labor with Slavs. More widely, before 1500, the Indian Ocean with its Arab and Muslim merchants had the largest volume of world trade and slave trade; after 1500 the Atlantic Ocean with its European merchants and African collaborators became more and more a center of world trade as well as of slave trade.

The New World

The making of the European "New World" was predicated upon the procurement of coerced labor. Even Columbus realized early on that he would have to generate riches and not just to steal them from Native American cultures. Schemes for a quick and gushing fortune required a lot of drudgery, which nearly all

explorers and planters had come to the Americas to avoid. Parasitically, they at first tried to use the Native Americans as their slaves, but the Columbian exchange of diseases decimated that source of labor. Accustomed to "European" diseases because of international trading contacts, enslaved Africans increasingly replaced sick and dying Native Americans, particularly in coastal, tropical, and disease-ridden areas prime for growing sugar and other lucrative crops. This switch to African labor in the Americas took a while, however.

From 1500 until 1650 slave trading was not the main activity along the western African coast that it would become later. The Portuguese, who initiated European contacts with western African kingdoms, were there mainly for the gold and, to a lesser extent, for pepper, ivory, and leopard skins. Elmina Castle in Ghana began as an entrepôt (intermediary center of trade and transshipment) for precious metals and other exotic luxuries in the 1480s, but it eventually became a factory for holding slaves for exports. It was taken over by the Dutch in 1637. By 1700 the Swedes, Brandenburgians, Danes, Britons, French, and the Dutch had established similar factories along the western African coast that was formerly devoted to the gold trade. Elmina Castle itself became less significant as rivals such as Cape Coast Castle took away more and more of the business themselves.

This illustration from a U.S. missionary book, which shows Africans being taken into slavery by African Muslims, is notable for the absence of white traders.

The slave trade became the most contested type of mercantilist capitalism whereby governmental monopolies from Europe tried to trade exclusively with African states one on one without any entrepreneurial inference from either side. For example, *asientos* were contracts by which Spain outsourced the work necessary to keep its American colonies supplied with slaves, particularly young adult men who were thought to be the best suited for arduous field labor by Europeans. Starting in 1518 the Spanish Crown licensed favored companies, usually Portuguese, for a fee to bring in a quota of young adult men. Women (who performed most of the farm work in western Africa), children, and the elderly could be counted only as fractions toward fulfilling the fixed, contracted number. After other European countries besides Spain and Portugal realized that colonies could be viable only with African slavery, they set up their own

slave-trading monopolies. The English Parliament commissioned its own Royal African Company for that purpose in 1672 after a venture in the 1660s had failed. Parliament limited participation to merchants from London. Although leading to unprecedented profits for London-based merchants, this policy of limited participation enraged merchants from other ports such as Bristol, who, in turn, lobbied successfully to have the monopoly ended in 1698. The Royal African Company, however, continued to be a major player in the business until it was absorbed into another yet another licensed company in the 1740s. The actual profits from the slave trade were smaller than people thought at the time. A few merchants tripled their investment on the Middle Passage (the voyage of African slaves to the Americas), but that was the talked-about exception rather than the rule. On average the overhead, the constant turnover in personnel, and the unforeseen dangers due to on-board rebellions and bad weather reduced the yield to the standard 10 percent, which was in line with the yields of less exotic ventures. Thus, on their own, the profits from slavery and the slave trade were not enough to make Britain the first industrial nation, but they were enough to add to the demand needed to make it the first full-blown consumer society. At any rate, during the eighteenth century, when this trade was at its height, Britain dominated the export and transfer of enslaved Africans to the Americas. After the Treaty of Utrecht in 1713, the British gained the *asientos* of the Spanish Empire in addition to their own factories and markets. The guinea, a large-denomination British gold coin, was named for the lucrative nature of the slave trade along the Guinea coast.

Guns

Yet, even the British, with their maritime superiority, relied heavily on the eager and self-interested participation of African governments and elites out for their own profits. The disintegration of the Songhai Empire in Sudan after 1591 stimulated the further political fragmentation of western Africa into more than three hundred microstates and even more

Slave trade map of equatorial Africa, 1887, drawn by Arthur Cornwallis Madan. New York Public Library.

stateless societies, which, in turn, set the stage for numerous territorial and religious wars fueled by the introduction of guns into the area by the Portuguese. Local rulers wanted more guns, particularly after 1650 when the accuracy and durability of guns improved dramatically. In order to get these guns, rulers traded gold initially and later mostly prisoners from neighboring clans and countries. Farther south, one ruler of the Kongo kingdom, Nzinga Mvemba, tried to use the Portuguese against internal opposition and neighboring rivals. He and members of his family even converted to Christianity to cement this alliance. Of course, this fighting within and outside Kongo produced prisoners, stimulating more Portuguese interest and involvement in the country than the ruler had originally wanted. He moved to confront the Portuguese, but it was too late. After the Portuguese had insinuated themselves into Kongolese trade, he could not preclude the long-term effects of

civil war, resulting famines, and the slave trade upon his country. The Europeans also needed African help in part because of the disease environment, for which they were not prepared. Most sailors and agents along the western African coast never returned home to enjoy what little income they had gleaned from the slave trade. Because yellow fever and malaria were dangerous to their own European employees, both governments and freelancers preferred African and biracial (of mixed white and black ancestry) contractors who could work at interior trading posts without getting sick.

Overall, the transatlantic slave trade, with its infamous Middle Passage, ensnared roughly 11 million people between 1443 and 1870. Historians continue to debate the exact number of slaves, but the difference in numbers largely comes about because of the question of at what point in bondage historians should start counting. In 1969 Philip Curtin, using

slave ship and archival records, published the first well-documented attempt to count how many people were enslaved by the transatlantic slave trade. More recently other scholars have pointed out that if historians use only slave ship records that show how many of the enslaved boarded for the Middle Passage, that leaves out the millions more who perished in forced marches to the coastal factories. The historian Joseph C. Miller has noted that, in reference to the Angolan slave trade, only 64 percent of the people initially detained would actually make it alive to the slave pens of Luanda for embarkation to the New World. However horrific and brutal itself, the Middle Passage was truly only a transition from frequent fatalities along the trails to the ships to even more mortality after slaves were in the Americas, particularly after they were in the death traps of sugar plantations and precious metal mines. Miller estimates that two-thirds of those people seized in Angola during the late eighteenth century would have died by the fourth year of being a slave on a Brazilian plantation.

Demographics

Slaves became increasingly male, younger, and hailed from more southern locations in Africa by the nineteenth century. As David Eltis and David Richardson have recently concluded, “the demographic

characteristics of the coerced migrant flow from Africa changed from one of rough balance between males and females and the presence of some children in the seventeenth century, to one in which males and children predominated by the nineteenth century” (Eltis and Richardson 2003, 55). This relative lack of enslaved women for export spared western and central Africa from complete demographic and economic collapse, but it failed to mitigate the long-term underdevelopment decried by the scholar and activist Walter Rodney. The triangular trade of guns for slaves to produce druglike staples for a world market addicted African kings and elites to European weapons and manufactured goods and thus inhibited the growth and enhancement of local industries outside of slave trading. When the slave ships stopped coming, local leaders scrambled to find appropriate substitutions.

Indeed, after European countries and the United States started to abolish the transatlantic slave trade after 1807 and then slavery itself after 1833, slave trades were again primarily associated with interior Africa, the Islamic world, and the Indian Ocean basin. Although Brazil and Cuba would continue to import slaves long after other plantation societies had ceased to do so, slave trades actually increased most in volume and frequency within Africa after 1800 as jihads proliferated and sellers looked for alternative

A free race cannot be born of slave mothers. • Margaret Sanger (1879–1966)

markets. Most deceptively, a most virulent wave of European imperialism in Africa and Asia during the late nineteenth century was rationalized in part as an effort to stamp out slavery and slave trades. Accordingly, slave trades today are met with disapproval from the global community, with the genocidal wars in the Sudan and its enslavement of captives being the most glaring instance.

Smith, Adam

(1723–1790)

SCOTTISH ECONOMIST

Adam Smith, a famous eighteenth-century Enlightenment economist, is considered the father of modern economic theory and the principles of capitalism. The comprehensiveness of his book *Wealth of Nations* has ensured its continued importance in the field of economics.

Adam Smith was born in Kirkcaldy, Scotland, in 1723 as the posthumous son of a customs comptroller. The only child of a widowed mother, he remained very close to her to the end of her life. Smith never married, but kept a steady company of friends, including the philosopher David Hume and the historian Edward Gibbon.

After spending his early years at home, he matriculated at Glasgow College in 1737 at the age of fourteen. After three fruitful years at Glasgow he went on to Oxford University, which was a disappointment. Like contemporary Scottish intellectuals, Smith found Oxford University to be anti-Scot, stagnant and uninspiring, and generally unfit to promote intellectual activity. However, he stayed at Oxford for six years, and was less critical of it than his contemporaries. His studies through the years covered mathematics, Greek, Latin, moral philosophy, and other topics. In 1746 he returned to Kirkcaldy and his mother, with whom he stayed, unemployed, for two years.

In 1748 Smith successfully started as a lecturer at Edinburgh University. In 1751 he obtained the Chair of Logic, and one year later the Chair of Moral Philosophy, a position he held for twelve years, during which he wrote his first significant work, *Theory of Moral Sentiments*, published in 1759 to popular acclaim. The *Theory* was based on his university lectures and focused on morals for the common man,

based on the concept of “fellow-feeling.” Crudely explained, fellow-feeling is our imagining the feelings of another person reacting to a situation, thus feeling a milder version of his feelings. That feeling gives rise to sympathy, and through that, to righteousness or its opposite. As an example Smith mentions our sympathy for a man whose son has been killed; we sympathize with, or fellow-feel the pain of his loss as we imagine our feelings if it was our son, and we naturally approve of his wish for justice and revenge. Right action in this case is seeking justice, which for Adam Smith includes revenge, in a manner approved by the general audience. It causes the feelings of righteousness in others because the sense of fellow-feeling makes them feel that there is a right response, in this case justice and revenge. If the man’s son instead died from an incurable illness, the general audience would sympathize with his loss as before, but it would give rise to general feelings of disapproval if the man wanted to see the doctor hanged, as the doctor had done nothing wrong. The feelings of righteousness thus depend on what appears to the general audience to be an appropriate response to a given situation. Right action is thus the action that naturally gives rise to general feelings of righteousness, while wrong actions are those that give rise to general disapproval.

In 1764 Smith gave up his position to become tutor to the young Duke of Buccleuch on his two years’ tour of Europe, mainly France and Geneva. It gave Smith the opportunity to meet with famous French *philosophes* such as Turgot, Rousseau, and Voltaire, and to participate in the famous salons led by the leading ladies of Paris (one of whom reputedly fell in love with him).

Stipple engraving portrait of Adam Smith, 1805.
Library of Congress.

The beginning of the tour was less auspicious. During nine months in Touraine Smith found little intellectual stimulation and started to write a new book to fight boredom. It took ten years before it was published, but it became his lasting legacy, *An Inquiry into the Nature and Causes of the Wealth of Nations*, commonly known as *Wealth of Nations*. It is debated whether Smith's *Wealth of Nations* was a truly original work, or simply a structured compilation of economic thoughts making their way round the Parisian salons. Certainly, France acquainted Smith with both defenders and attackers of the economic theories of physiocracy (economic theory, originally promoted by Quesay, court physician to Madame Pompadour, promoting the theory that land and agriculture is the only basis of real wealth) and mercantilism, and probably his own later attacks were at least inspired by the criticisms already prevalent.

In 1766, Smith returned to Britain, visiting London for six months, then on to Scotland. There he continued his work on the *Wealth of Nations*, wrote other minor works, and oversaw new editions of his *Theory*. During those years, Smith held no formal positions, although attempts were made to get him a new tutorship or a position with the East India Company.

The publication, in 1776, of *Wealth of Nations*, universally admired for its theories and the quality of its writing, brought Smith to the academic forefront. It is debatable whether Smith changed his concept of human nature from his *Theory* to the *Wealth of Nations*. In the latter he clearly states that self-interest is rightly the basic motivation of human action—especially economic action—while the former is more unclear as to whether self-interest alone is a basis for moral action. The discussion is of particular interest to those who argue that the ideas in the *Wealth of Nations* came from the French *philosophes*. Whether Smith is considered original or not, it must be conceded that his work gave the clearest organized presentation of those ideas and brought them from the specialized discussion forums to the general reader.

Smith focused on topics such as the division of labor, self-interest as the main principle of economics, national wealth as represented by production capacity rather than by stocks of gold (introducing in a rough form the concept of gross national product), free markets, a theory of real price, a theory of rent, and not least, the principles of the market forces. In short, he described the theoretical basis of the economic system known today as capitalism. Notably, his theory of the division of labor did not consider the new industrial revolution, but was entirely based on human labor. His most famous example is that of the pin makers. He explains how one man completing all the processes of making a pin by himself can produce a maximum of ten pins a day, while ten men cooperating and specializing in each part of the process can produce 48,000 pins a day. The advantage of specialization is made clear, but it is characteristic

It is not from the benevolence of the butcher, the brewer, or the baker, that we expect our dinner, but from their regard to their own interest. We address ourselves, not to their humanity but to their self-love, and never talk to them of our own necessities but of their advantages. • Adam Smith (1723–1790)

of Smith that he was aware of disadvantages as well, and pointed out that the workers in time became bored and lost the feeling of connection to their work, a problem that Karl Marx dealt with nearly a century later. While his theories on specialization, self-interest, national wealth, and market forces have generally been accepted, those on real price as determined by the labor it takes to produce or procure an item and rent based on use and reasonable profit are commonly considered confused, a fact that he admitted himself. In total, however, the *Wealth of Nations* must be considered the first detailed work of modern economic theory, and its comprehensiveness has ensured its continued importance in the field of economics.

In 1778 Smith was made commissioner of customs for Scotland, which allowed him a comfortable salary for life, added to a pension from his old student, the Duke of Buccleuch, giving Smith economic liberty. His remaining years were mainly spent making revisions to his earlier works, especially the *Wealth of Nations*, and participating in discussions with his contemporaries. In 1784, his mother, with whom he lived most of his life, died, leaving him desolate and in rapidly declining health. In 1790 he published his last work, a new edition of his *Theory*, which was shortly followed by his death and the burning of virtually all his unpublished papers in accordance with his own wish.

Social Sciences

The discipline of social sciences typically includes anthropology, economics, political science, and sociology—although psychology and history sometimes find their way into the mix. The social sciences and history, however, especially world history, are natural partners since both study the same phenomenon: collective human life.

Scholarship and instruction at contemporary universities are organized into disciplines that are often grouped together into a comprehensive set of discipline types. In the United States, the division is often into natural sciences, social sciences, and humanities. The social sciences typically include anthropology, economics, political science, and sociology but the boundaries are not fixed. Psychology inhabits a borderland between social and natural science, and history is sometimes grouped with the social sciences and sometimes with the humanities. For example, an article on some aspect of indentured service in eighteenth-century America could appear in an economics journal, a political science journal, a sociology journal, or a history journal. At the same time, each social science discipline includes many subdisciplines, each of which has its own journals, scholarly meetings, and often their own paradigms.

Of all the social sciences, only history appears to go back to ancient times. But this is somewhat deceptive, because the social sciences existed in some form long before their modern names took hold, and history also went through a transformation in the nineteenth century. For example, Aristotle, Mencius, Li Si (Li Ssu), and Machiavelli were political scientists long before the term *social science* was coined, while

the modern historical method dates only to the nineteenth century.

The Natural Sciences

The social sciences emerged as modern disciplines after the natural sciences and in imitation of them. In English, though not in other languages, the word *science* used alone generally refers to natural science, which tends to put the social sciences in the position of having to defend their right to be called sciences. Social science can best be understood in its dual aspect as an imitation of natural science and in contrast to natural science.

Humans have acquired knowledge about nature and about each other since before they were fully human. More systematic knowledge was developed by literate civilizations around the world in the last millennia BCE. In spite of the considerable achievements of the Arabs, Babylonians, Chinese, Egyptians, Greeks, and others, the natural sciences in their modern form did not emerge until the scientific revolution of the seventeenth century.

Two remarkable characteristics of modern natural science are its high degree of consensus about method and the rapid advance in the creation of knowledge. Scientists are largely in agreement about what is known in their field, what the problems are, how to go about solving those problems, and what constitutes a solution. This consensus is now often called a *paradigm*, a term coined by the historian and philosopher of science Thomas Kuhn in *The Structure of Scientific Revolutions*.

The social sciences do not generally operate within such agreed-upon paradigms. If a new disease appears

An anthropology student sorts artifacts recovered from an archaeological site. He is part of a team studying traditional farming techniques and social life in eighteenth-century New England.

in the world, scientists can usually figure out the cause, how it is spread, and some of the measures to take to prevent the further spread. By contrast, when war breaks out, the level of consensus among social scientists is far lower and the approaches they take to explain the war are much greater.

From Natural Science to Social Science

Newton's success in formulating a universal law of gravitation made a great impression on thinkers in the eighteenth century, spawning numerous attempts to create an analogous science of human society. The philosopher David Hume (1711–1776) aspired to become the Newton of what he called the “moral sciences,” while the early nineteenth century utopian socialist Charles Fourier (1772–1837) believed he was the Newton of psychology. The most successful of these Newtons was Adam Smith (1723–1790), the founder of modern economics. In 1776, he published *Wealth of Nations*, which set out to explain the circulation of goods in human societies. For Smith, the force that moved goods was self-interest, just as gravity was the force that moved heavenly bodies.

The ever-increasing success of the natural sciences in the nineteenth century intensified the call for a science of society. Auguste Comte (1798–1857) was the most famous propagandist for a new social science.

Comte argued that human thought went through several stages, culminating in a scientific stage. Different areas reached the scientific stage at different times. Now, Comte argued, it was the turn of *sociology*, a term he coined for the new science of society. Comte is often believed to have advocated that sociology imitate physics, but Comte did not believe that there was just one method for all the sciences. Instead, he believed that each field had to develop its own method. Physics was mathematical, but biology, Comte believed, had its own nonmathematical method, and he argued that sociology would have to develop yet another method.

Another important difference between the natural and the social sciences is that unlike physicists and biologists, social scientists may inadvertently change the humans they study. When an entomologist studies wars among ants, no matter what she learns, it will not affect how and when ants conduct war, but when a political scientist or sociologist studies human war, the results may alter human behavior and even negate the results of the study.

Professionalization and Specialization

In the nineteenth century, the sciences became increasingly specialized, professionalized, and institutionalized. Men, and it was almost always men,

became fulltime physicists, chemists, or biologists. Departments were set up at universities, and journals specializing in a single discipline were founded. The modern scientific disciplines were born, and as the twentieth century progressed, subdisciplines multiplied. Scientific knowledge, both theoretical and practical, increased rapidly. Science became one of the pillars of modern industrial civilization. The social sciences followed the same course as the natural sciences. By the end of the nineteenth century, various fields of social science—anthropology, economics, political science, psychology, and sociology—had achieved the institutional form we now typically encounter as departments in colleges and universities.

Anthropology

Anthropology is usually divided into physical anthropology and cultural anthropology. Physical anthropologists, who study the physical characteristics of human beings in all their variability, generally reject race as a biological category and concentrate instead on complex genetic variability. This can be very useful to historians—for example, DNA evidence can help trace human migrations for which there is inadequate documentary evidence.

For cultural anthropologists, culture includes all the ways humans learn to behave. They are best known for studying the culture of “primitive” peoples—small, nonliterate societies. Among their discoveries is the finding that the people who live in these simpler societies are quite complex in their ways of life. In the latter part of the twentieth century, as isolated small societies became scarce, anthropologists began to adapt their techniques to more modern societies, and the anthropological definition of the term *culture* entered into common language, as in “Latino culture” or “corporate culture.”

The findings of cultural anthropologists are of great interest to world historians, who are interested in the progression from one type of society to another. By looking at hunter-gatherers now, or in the recent past, historians can catch a glimpse of how all humankind lived before the development of agriculture. By

reading studies of autonomous horticultural societies and of larger chiefdoms they can see how more complex politics developed as sovereign units became larger.

Economics

As Adam Smith said, economics is the study of how goods and services circulate. Most economists study market or capitalist economies in which exchanges of goods and services are largely voluntary, and even when economists study non-market phenomena, such as taxes and government services, they use techniques adapted from studying markets. Of the social sciences, economics is the most like a natural science. Economists use mathematics extensively and most work within an agreed-upon paradigm.

Economics is usually divided into microeconomics and macroeconomics. Microeconomics is the study of markets for individual goods and the behavior of individual economic units, including both individuals and companies. Macroeconomics is the study of whole economies, usually at the level of a country, but including international economics. Macroeconomics is more relevant for historians, who often want to include a discussion of the economy in their studies.

History and economics meet in the well-established field of economic history, a subfield of both economics and history. Economic historians study one of the most important aspects of the human past, economic changes, using techniques of both economics and history.

Development economics, which studies how some countries became more developed than others and as a result have higher standards of living, is a related subfield. The questions it asks is of vital importance to the poor of the world, but also crucial to understanding how the world developed in the last two centuries.

Unfortunately there is no consensus among economists on the necessary and sufficient causes of economic development. Economic historians can teach us a great deal about how Britain became the first industrialized nation, but do not agree about why Britain, not France or China, was the first to industrialize.

The Social Sciences are good at accounting for disasters once they have taken place. • **Claude T. Bissell (b. 1916)**

Political Science

Political science, the study of how people are governed or govern themselves, goes back to Confucius and Mencius in China and Plato and Aristotle in Greece. These ancients were concerned with how the state worked and, more importantly, with how the state should work. The tradition of examining these questions continued with such familiar writers as Niccolò Machiavelli (1469–1527), John Locke (1632–1704), and James Madison (1751–1836). The intellectual descendants of these political theorists continue to work within the field of political science, and their subfield is called political philosophy. As its name implies, political philosophy is close to philosophy in method and content. It is also close to intellectual history, but there is a difference. A political philosopher and an intellectual historian may look at the same subject—for example, James Madison—but the political scientist will tend to look at Madison for what he can tell us about politics, while the historian will try to show how Madison's thinking is a product of his time. The modern field of political science emerged at the end of the nineteenth century. As the name implies, many of the new political scientists wanted to make the discipline more scientific. They wanted it to be more relevant and more empirical so it would be better able to study the state as it worked in reality. Most contemporary political scientists belong to this tradition and carefully study various aspects of present-day politics in a democracy, including voting behavior, the influence of lobbying, and the relationship of state and local governments. Some political scientists use mathematical techniques and, as in other social sciences, there is a lively debate within the field about just how scientific political science is. For the study of world history, the most important subfields of political science are political philosophy, international relations, and comparative government.

Psychology

Psychology, the study of both the mind and the brain, belongs to both the social and the natural sciences. Although the focus of psychology is on the individual,

not the group, it is considered a social science because the individual is embedded in one or more groups. Psychologists, like other social scientists, apply their knowledge to human problems, ranging from mental illness to career choices, and a large proportion of psychologists work outside of the university. Many aspects of psychology are of interest to historians. The study of the authoritarian personality can throw light on dictators and their followers; the study of the effects of stress on individuals and groups may help explain historical circumstances. Some findings of social psychology suggest reasons why human groups are sometimes vicious and sometimes altruistic. Psychohistory, a subfield of history, uses psychology's insights to illuminate the personalities of major historical figures such as Martin Luther (1483–1546), Mohandas Gandhi (1869–1948), and Adolph Hitler (1889–1945), as well as to analyze political movements. For students of world history, one interesting and controversial question is: how much has human psychology changed over time? Neither historians nor psychologists are agreed on whether, or in what ways, the human psyche is different now than it was two hundred or two thousand years ago. Here psychology meets anthropology and we can ask to what extent human psychology is the product of culture.

Sociology

Sociology is the study of human groups from the very small to the very large. Unlike anthropologists, who generally study small traditional communities (*Gemeinschaft*), sociologists tend to study modern, relatively impersonal urbanized societies (*Gesellschaft*). They study myriad aspects of these societies, from marriage to bureaucracy to social mobility. In the nineteenth century, the founders of sociology formulated grand historical theories. Among the main practitioners of this proto-sociology were Comte (the inventor of the word *sociology*), Herbert Spencer (1820–1903), a social Darwinist who popularized sociology, Karl Marx (1818–1883), and Alexis de Tocqueville (1805–1859). Each of these thinkers explained historical change, mainly European historical change, in terms of a different but broadly

evolutionary general theory. In the late nineteenth century sociology became an academic discipline because of the work of men like Emile Durkheim (1858–1917) in France and Max Weber (1864–1920) in Germany, who retained a broad historical outlook while abandoning the interesting but unproven grand theories of their predecessors. A classic example of the use of sociology to illuminate historical trends is Weber's famous work *The Protestant Ethic and the Spirit of Capitalism*, which shows how the Protestant mentality contributed to the rise of capitalism.

The nineteenth century saw numerous attempts to understand the problems of society: poverty, crime, race, social conflict, and so forth. At the same time, more systematic ways of examining such problems were undertaken and governments began to publish more systematic statistics. In the twentieth century, as sociology became a profession, sociologists began to develop more rigorous approaches to the study of society, and especially of social problems. Sociology, as it developed in the twentieth century, can be contrasted with economics. Economists assume a society made up of rational individuals, each of whom is trying to maximize her or his personal well-being. For sociologists, economic interactions are important, but sociologists are interested in how they are embedded in wider social interactions. Economists generally believe voluntary exchanges between free individuals are mutually beneficial. Sociologists, on the other hand, emphasize that free exchanges are not so free because they are constrained by all sorts of social conditions such as the inequality of power and social norms. Sociologists stress that people are not poor or "deviant" because of their personal deficiencies. They are interested in the fact that some individuals and groups have more power than others and in the way they use their power to dominate and gain the material and psychic advantages available in their society. Not surprisingly, sociologists are often critical of society as it is.

A Natural Partnership

The social sciences and history, especially world history, are natural partners since both study the same phenomenon: collective human life. Unfortunately,

much of the time they travel in separate compartments. This is partly due to the high level of specialization of modern scholarship. It is difficult to keep up with the main developments of even one discipline, and keeping up with several is beyond any person's capacity. Interaction between fields of study is also difficult because different disciplines have very different ways of approaching how humans interact. But it remains important for world historians to learn from and use all the social sciences.

Sociology

Auguste Comte (1798–1857), the French philosopher who coined the term “sociology,” defined it as the systematic study of society, and the accumulated knowledge resulting from it, that would help to guide and improve social development. He advanced a “law of three stages”—not about “savagery–barbarism–civilization” but about three stages in the development of human knowledge: theological, metaphysical, and scientific.

Had sociology stayed true to its origins, it would be more central to the study of world history than it now is. Like most bold statements, that one needs to be immediately qualified. It is rarely possible to pinpoint, chronologically or geographically, the absolute beginnings of a broad intellectual tradition. Geographically, it has to be recognized that there were, and are, many different national sociological traditions, and concerns with history—let alone world history—have not been central to all of them. Chronologically, a key insight in comparative history and sociology—the analogy between the interconnected institutions of a society and the interconnected parts of a living organism—can be traced back as far as Aristotle’s *Politics*. Sociologists are also fond of tracing their ancestry back to Ibn Khaldun’s *Muqaddimah* of about 1380 (1958); often described as a “philosophy of history,” it is also one of the earliest discussions of the possibility of a social science and of long-term social change in world history, and it introduced concepts of undoubted sociological significance, such as *social cohesion*.

Precursors

The emancipation of sociology from the shackles of political and moral philosophy that it shared with so many other disciplines in the humanities and social sciences is usually seen as beginning in the French and Scottish Enlightenments and gaining momentum through evolutionary thinking in the nineteenth and early twentieth centuries. Through a study of history since classical times, in his *De l’esprit des lois* (The Spirit of the Laws), first published in 1748 (1949), Montesquieu distinguished between three forms of government—republics, monarchies and despotisms—less on the basis of who exercised power and still less on their respective moral qualities, and more according to *how* it was exercised and *why* each form arose to fit societies of different kinds. Other precursors of a historically orientated sociology include Adam Ferguson (1723–1816) and the Marquis de Condorcet (1743–1794). Ferguson stressed the interdependence of people with each other in societies, and in his *Essay on the History of Civil Society* (1767) he traced humanity’s progression from “savagery” to the “refinement” of “civil society” (the idea of “civil society” returned to great prominence in the late twentieth century, especially in connection with the collapse of Communist regimes in Eastern Europe). Condorcet’s *Esquisse d’un tableau historique des progrès de l’esprit humain* (Sketch for a Historical Picture of the Progress of the Human Mind, 1795 [1795]) similarly traced the entire progress of human society through a series of ten stages from “savagery”—when humans were little better than the animals—to

The only thing you will ever be able to say in the so-called 'social' sciences is: "some do, some don't." • **Kelvin Throop III** (twentieth century)

a vision of an egalitarian and enlightened future. Ferguson and Condorcet's visions of uninterrupted human progress set a pattern for many nineteenth-century theories of social evolution, in which human societies traveled from savagery through barbarism to civilization.

Auguste Comte—The Law of Three Stages

Montesquieu, Ferguson, and Condorcet were only “precursors” of sociology, however, in at least a literal sense, since the word *sociology* had not yet been invented. The dubious honor of coining the term belongs to Auguste Comte (1798–1857). Perhaps more clearly than anyone before (unless it were Ibn Khaldun), Comte was concerned with the possibility of a social *science*, the systematic study of society and the accumulated knowledge resulting from it that would help to guide and improve social development. He called this science “sociology.” At that time the modern division of the social sciences into many institutionally distinct disciplines—anthropology, archaeology, economics, political science, psychology, as well as sociology *per se*—had not yet come about, so it must be understood that by sociology Comte meant the social sciences at large, including

the study of world history. He advanced a “law of three stages,” but it was not about savagery–barbarism–civilization; it was rather about three stages in the development of human knowledge. At each stage a different general principle predominated in the ways in which human beings sought explanations of the natural and social world that they inhabited. During a long *theological* stage, explanations were offered in terms of gods and spirits. There had followed a *metaphysical* stage, when explanations were offered in terms of abstractions such as “reason”; this transitional phase was fairly clearly modeled on Renaissance and Enlightenment thought in Europe. Finally, the modern world was witnessing the emergence of a *positive* or *scientific* stage; in the early nineteenth century the word *positif* was nearly a synonym in French for “scientific.” Comte used it to signify the rejection of the speculative philosophy of the past, which had so often advanced propositions in forms incapable of being tested against observable facts. But Comte, the founder of philosophical positivism, was by no means a positivist in the sense that was later caricatured as “crude positivism.” He did not believe that scientific knowledge could be based on observation alone; observation had to be guided by theoretical ideas, but theories had to be modifiable in the light of observation. The corpus of knowledge

Auguste Comte, Herbert Spencer, and Karl Marx, some of the founders of modern sociology.

grew through the interplay of the two mental operations directed at theoretical synthesis and at the observation of empirical particulars. The law of three stages was linked to Comte's notion of a "hierarchy of the sciences." Looking at the history of the main areas of knowledge, he contended that the positive or scientific stage had been reached first in mathematics (which at that date was mistakenly believed to be an empirical discipline), then by astronomy, physics, chemistry, and biology; topmost in the hierarchy and last in development came the new discipline of sociology. The areas of knowledge higher in the hierarchy could not be *reduced* to the lower but represented a higher level of synthesis, the attainment of the scientific stage at lower levels being preconditions for the emergence of the higher. Astronomy had in Comte's view entered the scientific stage in antiquity; physics and chemistry had been placed on a scientific footing much more recently; the biological sciences were undergoing rapid development in his own lifetime. Each advance up the hierarchy of the sciences represented an increase not only in humankind's understanding of, but also in its control over, first physical, then organic, and finally social forces. In industrial society, when sociology had attained the scientific stage, social affairs would be studied and then regulated scientifically. Comte encapsulated this idea in his slogan *savoir pour prévoir, prévoir pour pouvoir* (know in order to foresee, foresee in order to be able [to act]). These central ideas of Comte's—despite there being a fairly high proportion of nonsense in his voluminous writings—contain a valid kernel that is still relevant to understanding world history.

Comte's influence was especially marked on the work of Herbert Spencer (1820–1903), who combined it with newly prevalent evolutionary ideas to produce an ambitious comparative-historical taxonomy of the forms of human society. His influence was in turn strongly felt in the development of sociology in the United States (for example, through William Graham Sumner, 1840–1910) and (with Comte) in the work of Emile Durkheim (1858–1917). In the student textbooks, Durkheim, Karl Marx (1818–83), and Max Weber (1864–1920) are now often depicted as the

three founders of the modern discipline of sociology (a curiously unsociological view that diminishes the extent to which they all stood on the shoulders of giants). Yet all three continued their precursors' central concern with understanding the long-term development of human society, so it is paradoxical that in the science they are supposed to have founded this concern became steadily less important as the twentieth century ran its course. The decades after the World War II saw the spread of what has variously been called "developmental agnosticism" (Wittfogel 1957), "hodiecentrism" (Goudsblom 1977) and the retreat of sociologists into the present (Elias 1987). This tendency may in part be the outcome of the sociological profession's wish to measure its achievements against the utilitarian yardstick of usefulness in rectifying the ills of contemporary society. It also had deeper intellectual roots.

The Retreat into the Present

The fact that in the Victorian age, and for some decades in the early twentieth century, there was a widespread and uncritical assumption that the new "civilized" industrial societies were *superior* to other ways of life—especially those that Europeans encountered in their colonies and Americans in the course of their westward expansion—led to an equally uncritical and comprehensive rejection by sociologists (and even more strongly by anthropologists) not just of the idea of progress, but of all study of processes and stages of long-term social development. The genocides of the Nazi era served as the most awful warning of the dangers of regarding categories of human beings as superior and inferior; Sir Karl Popper (1945, 1957) and Robert Nisbet (1969) forged intellectual links between political tyranny and the pursuit of "inexorable laws of historical destiny," which helped for a while to make developmental perspectives almost taboo for many sociologists.

The retreat into the present, however, had begun earlier. The rise after the World War I of the approach within anthropology known as "functionalism," associated especially with Bronislaw Malinowski and

A. R. Radcliffe-Brown, had a strong but markedly delayed impact on sociology. Functionalism involved studying societies as systems of well-meshing “parts” at a given point in time. It was at the peak of functionalism’s influence in sociology during the two decades after the World War II that Talcott Parsons (1902–79) dominated American sociology, and American sociology dominated the world. In anthropology, functionalism had begun as a methodological rule of thumb in field work: it was a reaction against the tendency of Victorian evolutionary anthropologists to resort to “conjectural history” in seeking to explain the customs of preliterate societies, when for the most part any firm evidence about the past of such societies was lacking. Seeking synchronic relationships between patterns that could actually be observed in the field made better sense for anthropologists than speculating about their origins in past time. Why the same ahistorical approach should have had such appeal to sociologists studying societies blessed with abundant written records of their own past development gives more pause for thought. Although functionalism was in retreat in sociology by the late 1960s, developmental agnosticism was then reinforced through the influence of French structuralism, which had drawn its original inspiration from the shift in linguistics from diachronic to synchronic investigations led by Ferdinand de Saussure (1857–1913). The same cast of mind can be seen in the so-called poststructuralist Michel Foucault (1926–1984), and its shadow falls even on the sociology of Pierre Bourdieu (1930–2002), two leading French intellectuals who have attracted numerous followers in sociology across the world. Foucault presents a particularly relevant paradox: he appears on the surface to be studying processes of historical change, but on closer scrutiny he can be seen to depict the dominance of static “discourses” that are mysteriously supplanted through unexplained historical *ruptures* into new dominant discourses.

Historical Sociology

By the end of the twentieth century, there was a definite revival of historical concerns among sociologists,

although historical sociology was now generally seen as one among many minority interests or subdisciplines—rather than the central preoccupation that it was for many of the discipline’s founders. An interest in world history, or in very long-term processes of social change, is however the province of a minority of a minority, among sociologists as among historians. (Furthermore, it is sometimes difficult to distinguish between historically minded sociologists and sociologically minded historians.) A useful distinction can be drawn between two types of historical sociology. The first may be called simply the *sociology of the past*, in which sociological concepts and theories are used to investigate groups of people living in some specific period in the past. This kind of research does not differ fundamentally from research into groups of people living in the present: it is merely that documents form a larger part of the evidence than they would generally do in research into the present, for the very practical reason that dead people cannot fill in questionnaires or respond to interviewers. As against this sociology of the past, other sociologists seek to discern and explain longer-term *structured processes* of development.

The distinction is not hard and fast. For example, Norbert Elias’s *The Court Society* (2006)—among his works the most widely admired by historians—deals with a relatively closely defined place and period (France and its royal court in the century before the French Revolution), but his underlying concern is with more general processes of development. Still less is the distinction one of academic worth. Many of the finest examples of historical sociology are instances of the sociology of the past. To put it perhaps oversimply, their impulse is comparative rather than developmental.

The scale on which comparison is pursued or invited varies enormously. At one end of the scale, two widely admired books may be mentioned: Kai T. Erikson’s *Wayward Puritans* (1966) and Leonore Davidoff’s *The Best Circles* (1973), studies respectively of deviance in colonial New England and of behavior in nineteenth-century London high society. They are excellent examples of the sociology of the past. Their

value, however, is not dependent on the fact that they are studies of the *past*: they are in effect contributions to the understanding of deviant behavior and of endogamous status groups irrespective of time. The arrow of time may also be reversed for comparative purposes: a present-day study may prove stimulating when studying the past. For example, Stan Cohen's modern classic, *Folk Devils and Moral Panics* (1972)—a study of battles between rival groups of motorcyclists and motor-scooter riders in Britain and of the public reaction to them—might usefully be read by historians laboring at the large body of research on witch crazes in the past.

Other examples of the sociology of the past, but on a more macrosociological scale, are studies like Barrington Moore's *Social Origins of Dictatorship and Democracy* (1966) and Theda Skocpol's *States and Social Revolutions* (1979). They explicitly set out to study comparable episodes at different periods in different societies. Taking a small number of episodes, they attempt to generalize to similar situations, past, present, and future. Yet they do not advance any theory of social development over the longer term.

The minority of the minority are those sociologists whose interest centers on the construction of modes of long-term developmental processes. They include notably Immanuel Wallerstein, whose *The Modern World-System* (1974, 1980, 1989) is in effect a massive attempt at an historical disproof of David Ricardo's apparently timeless "law of comparative advantage." Wallerstein presents what is in effect a very long-term illustration of the principle of "path-dependency," showing how initially small inequalities in ties of interdependence between societies and economies have been magnified over time to produce huge differences today between what are euphemistically called the "North" and the "South." Another example is that of Norbert Elias, whose massive *The Civilizing Process* (2000 [1939]) advances a theory of state formation based on a study of western Europe during the second millennium CE and links that to changes in the psychological makeup (or *habitus*) undergone by individuals as they become gradually more subject in the course of generations to the social

constraint imposed by the monopolization of violence by the state apparatus. Charles Tilly's work also centered on state formation processes. Abram de Swaan's *In Care of the State* (1988) shows how the development of compulsory education, income maintenance, and public health policies followed a similar sequence over five hundred years in Britain, Germany, France, the United States, and the Netherlands, because a process of the collectivization of risk overrode very different ideological assumptions in the various countries. Michael Mann's *The Sources of Social Power* (1986, 1993) traces the changing relationship between economic, ideological, military, and political bases of power over the entire course of human history. Another large-scale intellectual project is that of Randall Collins, whose work, usually represented as "sociological theory," in fact replicates in scope that of Max Weber; representative books are *Weberian Sociological Theory* (1986), *The Sociology of Philosophies* (1998), and *Violence: A Microsociological Theory* (2008). Finally, it should be recognized that Marxist scholars kept alive the sociological interest in long-term processes of change when they were least fashionable. Perry Anderson's *Passages from Antiquity to Feudalism* (1974a) and *Lineages of the Absolutist State* (1974b) are classics of that tradition.

Perhaps in response to the hodiecentric mood that prevailed in their discipline for several decades—historical sociologists have shown considerable methodological self-awareness. Notable contributions in this area are Charles Tilly's *Big Structures, Large Processes, Huge Comparisons* (1984); the extensive debate about the relevance of rational choice theory in historical sociology (Coleman and Fararo 1992); that about the entire "scientific" basis of historical sociology provoked by Goldthorpe (1991, 1994; cf. Hart 1994, Mann 1994). William Seward's *Logics of History* (2005) and the collections of essays edited by Adams, Clemens, and Orloff (2005).

At what appears and may prove to be a turning point in world history—marked by the financial collapse of 2008—a concern with long-term processes may be returning to the center of sociological

concerns. In particular, the widely predicted decline in American world hegemony looks certain to provoke studies—such as *The American Civilising Process* (Mennell 2007)—of the United States in long-term perspective.

Socrates

(c. 470–399 BCE)

ATHENIAN PHILOSOPHER AND TEACHER

The ancient Greek philosopher Socrates was interested in seeking the authenticity of knowledge, and exemplifying and seeking moral integrity. The principal sources for his life and teachings are two of his students, Plato and Xenophon. Both wrote dialogue in which Socrates, as the central character, engaged a variety of people in conversation, the very method of teaching he espoused.

Socrates was born just at the time that Athens was beginning to experience empire; he grew as the Athenian Empire was growing; he survived the long and fratricidal war with Sparta, which destroyed Athenian power; he witnessed Athens's ultimate defeat; he was slain by a new democracy seeking to reestablish itself out of the ashes of the old.

For much of that time, he had acted as a teacher to the wealthy young men of the city, although without taking payment. He taught within a tradition of traveling thinkers and lecturers (Sophists), whose speculations about and interrogations of the natural world represented a genuine attempt to understand the structure and order of things. The style of these Sophists was deductive rather than experimental, and their consuming interest was the description of reality. Such men made their living as itinerant teachers and their reputation suffered principally because they had either to teach for pay or to accept the support of a wealthy patron.

While Socrates, superficially at least, belonged in this tradition, he was neither traveled (he lived his life in Athens) nor did he accept pay (despite apparent poverty). Furthermore, he was less interested in seeking to describe the natural world as he was in probing

the authenticity of knowledge, and exemplifying and seeking moral integrity. Moreover, he did not teach through exposition, but through relentless questioning of his subject. To Socrates, philosophy was, essentially, a conversation rather than a lecture.

For some decades, Socrates had lived a more or less conventional life. An Athenian citizen, he was wealthy enough to serve as hoplite in the Athenian army (the heavily armored hoplites provided all of their own equipment). As a warrior, he had distinguished himself in battle, serving with distinction in three bloody engagements during the Peloponnesian War: Potidaea, Amphipolis, and Delium. According to one story, he saved the life of the brilliant young politician, Alcibiades, at the Battle of Potidaea. At that time, Alcibiades was both his student and constant companion although not, surprisingly, his lover.

Socrates was married to Xanthippe, who bore him two sons. He also fulfilled other duties of a citizen. Socrates was serving as president of the Athenian Assembly in the days after the disastrous Battle of Arginusae. In this Pyrrhic victory, the Athenian fleet had triumphed over a Spartan navy, but a storm in the aftermath of the battle had prevented the victorious Athenians from returning to the site of the battle to collect the casualties in the water. As a result the generals were all accused together, a process which—although highly popular—was contrary to Athenian law. Socrates voted against the proposal, although without support. The entire board of generals was found guilty and executed.

Socrates again demonstrated his personal integrity when, after Athens's defeat in 404 and the imposition of a narrow pro-Spartan regime ("The Thirty Tyrants"), he refused a request to arrest a citizen charged

The unexamined life is not worth living. • Socrates (469–399 BCE)

Jacques-Louis David, *The Death of Socrates* (1787). Oil on canvas. In David's Neoclassical painting, Socrates calmly lectures on the immortality of the soul as he reaches to accept the bowl of hemlock that will kill him. Metropolitan Museum of Art.

with a political offense. Despite his public refusal to cooperate with the tyrants, he was never entirely free of political suspicion after their fall and the restoration of democracy, since a number of them had been his students. It was as much the political activity of his students, most particularly Alcibiades and Critias, as his iconoclastic teaching that led, in 399, to his being charged with impiety. This meant, for the purposes of the charge, bringing new gods into Athens and, more significantly, corrupting the minds of the young. Found guilty by the court, he was sentenced to death and executed through the administration of the poison hemlock.

Our principal sources for Socrates' life and teachings are two of his students, Plato and Xenophon. Both wrote dialogues in which Socrates, as the central character, engages in conversation with a variety of people. Curiously, Plato's Socrates and that of Xenophon are quite different people, with different views and different ways of speaking. They are both, in turn, quite different from the burlesque Socrates lampooned by Aristophanes in his play *The Clouds*.

Whether his views are accurately represented by Plato or Xenophon, or neither, Socrates remained

deeply influential, both in terms of his focus and his method. This is reflected by the fact that the Sophists who preceded him, and whose interests lay in understanding the natural world, are referred to as "pre-Socratics," and the dialectical method of teaching that he used is commonly referred to as "Socratic questioning." He himself wrote nothing, and thus his teaching can only be apprehended through the works of others. Whether he intended this or not, it seems, in retrospect, entirely appropriate.

Sokoto Caliphate

For nearly a century (c. 1808–1903) the Sokoto caliphate in West Africa extended a particular form of Islamic rule across much of the Sudanic region south of the Sahara and north of the West African forest zones. The state continued under British rule with more moderate leaders willing to submit to British authority, but the traditions of political Islam espoused by Sokoto's founder, Usman dan Fodio, still remain in northern Nigeria.

Formed following a successful jihad proclaimed by Usman dan Fodio (1754–1817) and initially led by his kinsmen, the Sokoto caliphate in West Africa was intended to be a theocratic state unifying Usman's people, the Fulani, and enforcing their political hegemony over other societies, especially the Hausa states that had previously dominated the region.

Origins of the Jihad

Himself the son of a Fulani teacher, Usman dan Fodio studied with a variety of *shaykhs* (Arabic: teachers, or *shehu* in the Hausa language) in the Qur'anic schools of what is now northern Nigeria. As his knowledge grew, so did his reputation among the Sufi Muslims who shared his devotion to the Islamic Qadiriya Sufi brotherhood popular in the region. He gradually amassed a following among the local population and attracted numerous students. Continuing to preach, he increasingly contrasted what he saw as the righteous path required of faithful Muslims with the

debased religious practices he believed were prevalent among the Muslim Hausa rulers in the region.

As his fame spread and the numbers of his followers grew, the local Hausa ruler of Gobir—a nominal Muslim—made efforts to prevent his further teaching. The situation deteriorated until conflict between Usman's followers and the state, ostensibly over the enslavement of Muslims, led to war in 1804. At that point, Usman dan Fodio began a series of pronouncements encouraging Muslims throughout the region first to flee (an action analogous to the Prophet Muhammad's flight to Medina) what he described as persecution, writing a number of religious and political tracts explaining his position and laying out his vision of proper Islamic governance. Eventually elected caliph amongst his Fulani followers, Usman then proclaimed a jihad of the sword against rulers who refused to adhere to what he described as the pure ways of Islam.

Establishment of the State

The warriors who responded managed to vanquish Gobir by 1808 and soon turned their attention to other Hausa states in the region. Many who had grievances against these states and their rulers came to the Usman seeking his approval for their efforts. To those whose cause he perceived as just, Usman gave a flag that announced that they waged their campaigns with his support. Yet he refused to proclaim himself the expected Madhi (a messiah figure) whom many Sufi Muslims believed would deliver the faith from its numerous challenges.

As wise in the ways of the world as he was in matters of the faith, Usman dan Fodio recognized that he was skilled neither at war nor the administration of a state. These tasks he delegated to his brother, 'Abd Allah bin Muhammad, and his second son, Muhammad Bello (1781–1837). They were the leaders who organized further military campaigns and later the decentralized state structure of Sokoto. Each conquered Hausa state was assigned to an emir who ruled under Usman's authority and in accordance with Islamic law, subject to removal if he deviated from that path. By some estimates, Sokoto was the largest African state anywhere on the continent in the early nineteenth century.

Supporters of Usman dan Fodio continued to plan for further expansion of the state. After his death in 1817, authority passed to Muhammad Bello, who ruled as the sultan of Sokoto, building upon his father's legacy. Also a literate and respected interpreter of Islamic tradition, his many writings continued the traditions previously established for the state and added to them, making the Sufi dedication to the expectation of deliverance by the Mahdi the prevailing orthodoxy of the state.

Internal Problems

During the middle of the nineteenth century, however, Sokoto was beset by many difficulties. Efforts to conquer the state of Bornu to the west were never successful, and Bornu's ruler objected in a letter to Muhammad Bello that the forces of Sokoto were not only attacking a people committed to reforming the faith but were enslaving Muslims captured there. (Slavery was not forbidden to Muslims and was practiced in many Islamic societies, but enslaving fellow Muslims was generally frowned upon.) Sokoto derived much of its wealth from slavery, both as a supplier of slaves for the slave trade and in its dependence on slave labor on its plantations and for the tending of its cattle. Some of these slaves were certainly Muslims.

These practices troubled some of Sokoto's religious leaders, but often seemed minor distractions to the

goal of maintaining an Islamic state. Political authorities paid greater attention to defeating numerous rebellions on the fringes of the state and also to dealing with dynastic struggles within the Sokoto elite itself and among emirs of its various quasi-independent provinces. These disputes were generally resolved successfully through traditional military means and thus, inadvertently, served to diminish any modernizing tendencies, which in any case were suspect in a conservative, theocratic state.

British Conquest

Although the Sokoto caliphate was among the most dynamic African political entities at the beginning of the nineteenth century, it was much less so at the start of the next. In Frederick Lugard (1858–1945), who was appointed high commissioner of the British Protectorate of Northern Nigeria in 1900, Sokoto confronted a challenge it could not easily match. Lugard did not favor a diplomatic settlement that might have avoided war, preferring instead a conquest, which

he assumed would be welcomed by the Hausa and poorer Fulani, whom he believed were disgusted by corruption and deviations from Islamic law. But he underestimated the nature and strength of belief even among the common citizenry.

Realizing the British might, even at great cost, defeat one Sokoto emirate after another, the sultan at that time, Attahiru dan Ahmadu (ruled 1902–1903), debated with advisers the best course to follow. But in March 1903 the British forced his hand, defeating his ill-equipped armies at the city of Sokoto itself and effectively bringing an end to the independence of the caliphate. The sultan, however, rallied all who would follow him—and there were many, to the surprise of British officials—in a flight toward Mecca to avoid submission to invaders they considered infidels. British forces tracked their progress and, in July 1903 during what some observers describe as a needless battle, the sultan and almost all who had joined him were killed.

The state continued under British rule with more moderate leaders who were willing to submit to British authority. But the traditions of political Islam espoused by Usman dan Fodio and put into practice during the century of independent rule in Sokoto still remain in the political culture of northern Nigeria. As the influence of British rule diminished late in the twentieth century and as local Islamic traditions

reemerged in their place, the impact of a strict observance of Islamic law continued into the twenty-first century.

Songhai

The Songhai Empire of the western Sudan came together from peoples whose livelihoods depended on the Niger; by the tenth century the empire thrived along both riverbanks and the bordering lands. During the sixteenth century, the Songhai city of Timbuktu (Tombouctou) was a great center of learning with hundreds of Qur'anic schools and many learned scholars. After some eight hundred years it lost independence to an invading Moroccan army.

The Songhai (Songhay) Empire was the third of the early great states of the western Sudan, preceded first by the Wagadu Empire (Ghana; flourished in the first millennium CE) and then Mali (flourished mid-thirteenth–mid-fifteenth century). The Songhai Empire was made up of many different peoples who gained their livelihood from the Niger River and its bordering lands. Fishermen called Sorko built and operated riverboats and canoes. The Gow hunted river animals such as crocodiles and hippopotamuses. People known as Do farmed the fertile lands bordering the river. All of these together came to be known as Songhai. The empire developed out of the Kingdom of Gao that had been established by the tenth century. By the second half of the fifteenth century the state was expanding along both sides of the Niger River, which flowed in a great curve through the entire country from west to east. At its peak, Songhai stretched from the area of Niore du Sahel, near the border of what are now southern Mauritania and western Mali, to Agadez in the modern Republic of Niger. In 1591, after some eight hundred years of existence in one form or another, this western

Sudanic state lost its independence to an invading Moroccan army.

Scholarship and Evidence from the Niger Bend

During the sixteenth century, when the Songhai Empire was at the height of its power, the city of Timbuktu (Tombouctou) was a great center of learning with hundreds of Qur'anic schools and many learned scholars writing on a variety of subjects. Until recently, the most highly regarded sources for the history of Songhai through the Moroccan invasion (1591) have been the seventeenth-century Timbuktu historians Ibn al-Mukhtar who wrote *Ta'rikh al-fattash* (Chronicle of the searcher) and 'Abd al-Rahman al-Sa'di, who wrote *Tarikh al-sudan* (Chronicle of the Sudan). John Hunwick translated the latter into English in *Timbuktu and the Songhay Empire* (1999). Another important new source for Songhai history is a large collection of inscriptions that were written on tombstones beginning as early as 1013 CE. These have been translated and studied by P. F. de Moreas Farias in his *Arabic Medieval Inscriptions from the Republic of Mali* (2003). Farias has convincingly called into question the historical accuracy of the Timbuktu chronicles. The Hunwick and Farias books are essential to any study of Songhai history.

The Kingdom of Gao

In addition to the people collectively known as Songhai, the camel-riding Sanhaja of the Sahara were prominent in the Niger Bend region. The Sanhaja,

known locally as Tuareg, settled on the left bank of the Niger at a place that came to be known as Gao, or, as the North African traders called it, Kawkaw. By the tenth century the Songhai chiefs of Gao established it as a small kingdom, taking control of the peoples that lived along its trade routes. Tombstone inscriptions mention two early Songhai dynasties, perhaps indicating simultaneous regional rule. The earliest, which dated from at least 1083–1084 CE went by the title *Muluk*, with queens possibly sharing power and bearing the title *Malika*. The other dynasty's rulers were known as *Za* or *Zuwa*, of whom the Timbuktu chronicles make the questionable claim that there were thirty-two (the alleged first *Zuwa* named Alayaman appears to be entirely mythical). Between 750 and 950, Gao became an increasingly important southern terminus in the trading of goods across the Sahara. Commerce in gold, salt, slaves, kola nuts, leather, dates, and ivory brought revenue from taxes that were levied on all goods moving in and out of the empire. Because of this rich trade, Gao became the capital of Songhai. Recently revealed evidence

indicates that Mali gained at least intermittent control of Gao toward the end of the thirteenth century and retained it into the first half of the fifteenth century. Sometime during Mali's hegemony a new dynasty took power, with the rulers carrying the title of *Sii* (a contraction of *Sonyi*, a Manding term). The earliest of the historically documented *Sii* was Sulayman Dama, who attacked the Malian province of Mema sometime before 1464.

Sii Ali Beerli (reigned 1464–1492)

Sii Ali Beerli expanded the kingdom of Gao westward throughout the Niger Bend and developed it into the Songhai Empire. Sii Ali had a large, well-disciplined army that included cavalry and a fleet of riverboats to transport troops. His imperial expansion included the conquest of both Timbuktu and Jenne, which became the second and third most important cities of the empire after Gao. Having won every battle he ever fought and holding power for twenty-eight years, Sii Ali died in 1492 while returning from a military campaign.

A modern warrior in a chain mail shirt from the era of the Songhai Empire sits astride a horse (Kano, Nigeria, 1965).

Askia Muhammad the Great (reigned 1493–1528)

In 1493 Sii Ali's son Abu Bakr Dao (Sii Baru) was defeated in battle by Muhammad Abu Bakr Ture, founder of a new dynasty whose leaders would be known by the title "Askia," which had been a rank in the Songhai army since the first half of the thirteenth century. Askia Muhammad's devotion to Islam brought relief to the urban Muslim populations who had at times been treated harshly by Sii Ali. The askiya's piety also contributed to his prestige and power when he went on pilgrimage in 1497–1498 and the Abbasid caliph of Cairo (not Mecca as it is usually stated) named him caliph, or commander of the faithful, in the western Sudan. As one of the greatest of the Songhai rulers, Askia Muhammad strengthened and extended the empire that had been created by Sii Ali. He created a professional full-time army and built up the Songhai cavalry, expanding Songhai's control far beyond the territories of the Middle Niger. Under Askia Muhammad the Great, as he came to be known, the Songhai Empire established tributary lands northward to the salt pans of Taghaza in the Sahara, westward to former territories of the

Mali Empire, and eastward to the Tuareg sultanate of Agadez. The empire eventually became so large that its army was divided into two, one for the western provinces based in Timbuktu, and one for the eastern provinces based in Gao. Having grown old and blind, Askia Muhammad was deposed by his son Musa in 1529, though he lived until 1538.

We know the names of thirty-seven of Askia Muhammad's sons by his various wives and concubines, though he is thought to have had many more. These sons were mostly half-brothers, and as they grew up they began to compete for power and to quarrel among themselves. Beginning with Askia Musa (reigned 1529–1531) and ending with Askia Ishaq I (reigned 1539–1549), the reigns of the four askiyas after Muhammad the Great were characterized by bloody struggles for power.

Askia Dawud and His Sons

Askia Dawud (reigned 1549–1582) is regarded as the third of Songhai's greatest rulers. He commanded many far-ranging military campaigns, and during the thirty-three years of his reign, as important offices became vacant, he appointed his own sons to the

positions, thus eliminating from high office the offspring of other sons of Askiya Muhammad. From his time forward, all Songhai's rulers were descendants of Askiya Dawud. However, after he died in 1582, warfare once again broke out among brothers competing for power.

With the exception of the sickly Askiya Muhammad al-Hajj (reigned 1582–1586), Askiya Dawud's sons continued the kinds of deadly power struggles that had characterized the reigns of Askiya Muhammad's offspring. In 1588, during the reign of Muhammad Bani (reigned 1586–1588), a bloody confrontation between two imperial officers at the Timbuktu port of Kabara led to a civil war that weakened the Songhai armies and contributed to the empire's subsequent vulnerability to outside invasion. In 1588 Askiya Ishaq II (reigned 1588–1592) came to power, and it was during his rule that Songhai suffered its most devastating defeat.

The Moroccan Invasion of 1591

In 1590, encouraged by a scheming runaway Songhai slave who claimed to be the askiya's brother, Sultan Mulay Ahmad of Morocco wrote to Askiya Ishaq II demanding, among other things, payment of tax on the salt mine of Taghaza, which was in disputed territory halfway between Songhai and Morocco. Askiya Ishaq II replied with a challenging message, which Sultan Ahmad answered by sending an expedition to attack Songhai. The Moroccan army set out at the end of 1590 with around four thousand fighting men both mounted and on foot, many armed with muzzle-loading firearms. They were led by Jawdar Pasha, an Islamic convert of Spanish origin who was a eunuch. The decisive battle between the Moroccan and Songhai armies took place on 12 March 1591 near Tondibi, 48 kilometers north of Gao on the Niger River. The Songhai army suffered heavy losses and retreated across the Niger River, shielded by a courageous rearguard that fought to the death.

Askiya Ishaq II offered the Moroccan invaders 100,000 pieces of gold and 1,000 slaves on the

condition that they leave Songhai and withdraw to Marrakech. When Sultan Mulay Ahmad heard that Jawdar Pasha was inclined to accept the peace offering, he replaced him with Mahmud Pasha, who fought and defeated Ishaq II late in 1591. Fleeing to the ancient Songhai homelands, Ishaq was deposed in favor of Muhammad Gao, who was later treacherously murdered by Mahmud Pasha. Under Nuh, a brother of Muhammad Gao, Songhai continued to resist the Moroccan occupation with guerrilla tactics. For two years they fought successful skirmishes against Mahmud Pasha and his troops. Failing to defeat Nuh, Mahmud finally gave up and returned to Timbuktu, but the Songhai were never able to recover their empire.

The Arma of Today's Mali

The Moroccan invaders established permanent garrisons in all the major cities of Songhai, including Gao, Timbuktu, and Jenne. The Arabic word for *shooter*, as the Moroccan musketeers were called, was *al-rumah*, so the occupying soldiers were called Ruma. Within a generation or so the Ruma lost their connection with Morocco, and by around 1700 there were few of their descendants who could speak Arabic. In the Songhai language Ruma evolved into Arma, the term by which the descendants of the Moroccan ruling elite came to be known. The Arma still form a social class in the cities of Jenne, Timbuktu, and Gao in the Republic of Mali.

Space Exploration

The quest for greater knowledge and understanding—as well as Cold War rivalry between the United States and the Soviet Union—fueled the modern space race in both unmanned and manned spacecraft, but humans have acknowledged the powers of the solar system since prehistoric times. Advanced technologies, and an increasing spirit of private enterprise, open possibilities for new adventures and frontiers.

Since the first people walked the Earth, the heavens have beckoned to the human spirit and inspired the human imagination. The drama of the sky has enthralled forty thousand generations of men and women. From prehistoric times, the sky and its celestial bodies have played key roles in mythology and religion throughout the world. Early American peoples, including the Aztecs of southern Mexico and the Anasazi of the North American Southwest, used the movements of the sun, planets, stars, and moon for calendrical and agricultural purposes and worshipped gods embodying the sun and moon. Similar religious trends emerged throughout the ancient world on every continent, and until the spread of monotheism, nearly every world culture worshipped some aspect of the sky. Hence, although the ancients had relatively little knowledge of the universe, they recognized the power of the heavens.

By medieval and early modern times, astrology, or the belief that the motion of the stars and planets shape the fates of individuals, kings, dynasties, and empires, was influencing the decisions of both political leaders and peasants. Not until the scientific revolution of the seventeenth century was the idea of the stars and planets as physical bodies obeying regular

laws accepted by influential people. For human space travel to become a reality, the work of Kepler, Newton, and Galileo first had to predict the movements and characteristics of bodies in space.

Early Development of Space Travel and Rocketry

Space travel didn't become feasible until the twentieth century. Rocket technology, which would become the basis of all space travel, began with the rocket development work of Konstantin Tsiolkovsky (1857–1935) in Russia and Robert Goddard (1882–1945) in the United States. The Chinese had invented a rocket weapon in 1232 using gunpowder, which was ultimately adopted in technologically sophisticated societies throughout the world. During the eighteenth and nineteenth centuries, various pioneers improved the rocket's effectiveness as a weapon. It is Tsiolkovsky of Czarist Russia, however, who is remembered as the “father of astronautics.” Although he dealt with many aspects of the rocket as an instrument of interplanetary travel, his most important contributions concerned propellants and the rocket design needed to achieve flight into the Earth's orbit and then farther into space. In particular, he discussed the possibility of powerful, controllable liquid propellants, such as hydrogen and oxygen, and multistage rockets. Although Tsiolkovsky accurately predicted many future developments, his writings were not widely read during his life.

The work of the U.S. physicist Robert Goddard also concerned multistage rockets and liquid propellants. In 1926 at a farm in Auburn, Massachusetts, Goddard used liquid oxygen and petrol to send the

first liquid-propelled rocket into the air at a rate of 60 miles per hour. He continued his experiments, with a launch in 1935 ultimately achieving 1,000 feet and a speed of 700 mph. Despite his genius and some financial support from the U.S. government, the reticent and publicity-shy Goddard did not contribute directly to the American space program. However, his reticence paved the way for the Transylvanian and German rocket and space travel visionary, Hermann Oberth (1894–1989), who corresponded with Goddard. Like Tsiolkovsky, Oberth dealt with both detailed engineering and the broader issues regarding space exploration. He helped to spread popular awareness of the rocket and the possibilities of space travel throughout Germany. In the 1920s and 1930s, various rocket societies in Europe and the United States, which included engineers as well as visionaries, met to build rockets as well as to advance their general knowledge of space travel.

Military Rocketry and the Imaginative Vision

Meanwhile, leaders in the USSR, building on Tsiolkovsky's ideas, formed a military organization in 1928 under young engineer Valentin Glushko (1908–1989). The laboratory, called the Gas Dynamics Laboratory (GDL), built solid-fuel war rockets. In 1931, Soviet leaders gained control of another key organization, the Group for the Study of Reaction Motion (known in the USSR as GIRD), which emphasized more powerful liquid-fuel rockets. GIRD had emerged from a core of Soviet engineers and space enthusiasts who dreamed of going to the moon and beyond. The Red Army funded this group as well as GDL. Sergei Korolev (1906–1966), the future mastermind behind the Soviet space program, was one of GIRD's most enthusiastic members. During this era, Korolev focused on rocket aircraft and honed his organizational skills. Through the efforts of GIRD, the USSR launched its first liquid-fuel rocket in 1933. Its success caused Soviet leaders to take a greater interest in the use of rocket technology in weaponry. Ultimately, leaders consolidated GIRD and GDL into

a single organization, RN-II, which made further contributions to rocket development. The tragic advent of Stalin's purges in 1934 threatened the nascent Soviet rocket program. Many Soviet rocket pioneers and space visionaries perished in the purges. Stalin's police imprisoned both Korolev and Glushko, but they managed to survive, working as state prisoners to advance rocketry.

In Germany, the state also harnessed space enthusiasts for military purposes. The most notable of these was Wernher von Braun (1912–1977), who would play a vital role in the United States space program as well as in the German rocket program. Born to a prominent family, von Braun was active in the VfR (Society for Space Ship Travel). He joined the German Army Ordnance Department in 1932 to work on a liquid-fuel rocket with a range greater than any preexisting artillery. In 1937, the group moved to Peenemünde, a new proving ground on the Baltic. Von Braun, who was talented as a manager as well as an engineer, led the rocket development program.

Although the Nazi leadership supported the program only erratically, von Braun and his associates made progress as they dreamed of future trips to the moon and Mars. The V-2/A-4 rocket, or "vengeance weapon," first flew in late 1942. It was much more powerful than any preceding rocket, standing almost fifty feet high, weighing 28,000 pounds, reaching a

Remains of an ancient observatory at Chichén Itzá, Mexico. Photo by Chris Howell.

To see far is one thing, going there is another. • **Constantin Brancusi (1876–1957)**

height of sixty miles, and carrying a heavy bomb. It burned liquid oxygen and ethyl alcohol and had sophisticated guidance and control systems. This rocket was an ancestor to many American rockets, including the powerful Saturn V which would take the first humans to the moon. Workers enslaved by Hitler built most of the V-2 rockets used in World War II. Although the weapons were not accurate, their victims had few defenses against them. In September of 1944, Hitler launched a V-2 bombardment against targets in southern England and liberated Europe. While powerful, these weapons made little difference to the war's final outcome.

Space Exploration and the Cold War

As the Cold War between the United States and the Soviet Union intensified after World War II, both the Americans and the Soviets utilized the survivors of Nazi Germany's military rocket teams. Stalin's rocket program, approved in 1947, was intended to culminate in the production of an Intercontinental Ballistic Missile (ICBM). The Soviet army recreated the V-2 rocket through the SS-I and SS-II rockets, but the Soviet aviation industry avoided rocket technology. The first Soviet ICBM, the SS-6/R-7, was built to carry the heavy Soviet nuclear warhead. However, its most significant flight occurred on 4 October 1957, when it launched the first human-made satellite, *Sputnik I*, into Earth orbit. As euphoria overtook the Soviet Union, the American public reeled in shock. If the Soviets were capable of launching a satellite to fly over American soil, were they not also capable of launching a nuclear weapon to the United States? And why hadn't the United States launched a successful satellite first? Nikita Khrushchev (1894–1971), who succeeded Stalin as Soviet premier in 1958, recognized the symbolic importance of Sputnik. The worldwide perception was that the USSR had overtaken the United States in science and technology; this implied military superiority.

As Americans panicked, President Dwight D. Eisenhower (1890–1969) remained secure in his knowledge of America's military superiority in the areas

of intermediate-range missiles, miniaturized nuclear weapons, bases near the Soviet Union, and spy planes. Just a year after Sputnik, von Braun's Army rocket team managed to launch the first American satellite, Explorer 1, with a modified Redstone rocket, the Jupiter-C. On 1 October 1958, Eisenhower announced the creation of the National Aeronautics and Space Administration (NASA), which would be based on the modest National Advisory Committee for Aeronautics (NACA). Although the military branches wished to carve out a place for themselves in the arena of space-flight, they would not hold responsibility for the high-profile manned space programs of the 1960s.

NASA's first mission, now that the Soviets had beat it into space, was to put a man in space first. NASA called the program Project Mercury. On 9 April 1959, NASA administrator T. Keith Glennan announced the names of the first seven American astronauts who would fly in Project Mercury. The American media and public went into a frenzy over the "Mercury 7," one of whom they believed would be the first man in history to orbit the Earth. Americans viewed the photogenic military test pilots as space warriors who, through their bravery, would save the United States from the spreading "red tide" of communism. In the USSR, however, Khrushchev and Sergei Korolev, the Soviet space program's chief designer, had likewise determined that a Russian should be the first man into space. Indeed, the Soviets won this particular race as well. On 12 April 1961, the cosmonaut Yuri Gagarin, in a *Vostok* spacecraft atop a new A-1 rocket, was launched into Earth orbit. The United States reacted strongly to the news, and NASA administrators and engineers accelerated the pace of Project Mercury.

The first American astronaut was Alan B. Shepard Jr. His fifteen-minute suborbital flight, launched on 5 May 1961, by the von Braun-designed Army Redstone rocket, did not match the Soviet achievement but it did put America back into the space race. However, the Redstone launcher, with a thrust of 75,000 pounds, did not have the power to place a manned spacecraft into the Earth's orbit. For this objective, NASA used the U.S. Air Force's Atlas ICBM, with a total thrust of 360,000 pounds.

National Aeronautics and Space Administration.

The Race to the Moon

Following on the heels of Shepard's flight, President John F. Kennedy (1917–1963) made a dramatic announcement to Congress on 25 May 1961. He called for the achievement of landing a man on the moon and returning him safely to the Earth before the end of the decade. Kennedy's announcement accelerated the space race because it gave an increased sense of national importance and urgency to NASA. The agency continued with Project Mercury, but it accelerated development of its lunar landing program, Project Apollo. In December of 1961, NASA announced Project Gemini, which would place two men into Earth orbit for extended periods. Gemini would practice many of the techniques used on Apollo, including

the rendezvous of two spacecraft, the docking of two spacecraft, and spacewalking.

NASA successfully launched astronaut John H. Glenn Jr. into orbit on 20 February 1962, in the Mercury spacecraft, *Friendship 7*. This flight required much more effort on the part of the astronaut, the flight controllers, and the spacecraft, which had to perform critical maneuvers and keep the astronaut alive for several hours. The Mercury program continued with three more flights, concluding with Gordon Cooper's successful 22-orbit flight on 15 May 1963. Mercury had achieved its major objectives of placing a man into Earth orbit and recovering him successfully.

NASA announced Lunar Orbit Rendezvous (LOR) as the Apollo mission mode in June of 1962. With LOR, von Braun's Saturn V rocket, with a thrust of 7,500,000 pounds, would propel a crewed spacecraft, a service module with supplies, and a lunar module toward the moon. Once in orbit around the moon, the lunar module would separate from the command and service modules, carrying two astronauts to the moon's surface while the command module pilot stayed in lunar orbit. The lunar module itself would have two stages, an *ascent stage* and a *descent stage*. When the astronauts finished their exploration of the moon's surface, they would return to lunar orbit in the ascent stage, leaving the descent stage on the moon, and dock with the command module. On approach to Earth, both the ascent stage and the service module would be jettisoned. Only the command module would return to Earth. Although NASA originally thought this method too risky, its weight-saving advantages and the fact that each component could be engineered independently for a particular purpose ultimately made it the most practical of the modes considered. The LOR mission mode determined nearly every aspect of Apollo development, from crew training to spacecraft design to spacecraft maneuvering systems.

Mercury astronaut Gus Grissom and "New Nine" astronaut John Young piloted the first flight of Project Gemini, on 23 March 1965. The Gemini spacecraft, while based on the Mercury spacecraft, was larger

and had a number of more sophisticated systems to allow performance in maneuvering, rendezvous, and docking. Later Gemini flights would dock with the Agena target vehicle, which was really the hollowed-out upper stage of an Atlas rocket fitted with docking adapters. But on 18 March 1965, Korolev dealt the United States another blow when Aleksei Leonov made the first spacewalk, lasting twelve minutes and nine seconds. Leonov and fellow cosmonaut Pavel Belyayev orbited the Earth in *Voshkod 2*, an updated version of Gagarin's *Vostok* spacecraft. Edward H. White III of *Gemini IV* performed the first American spacewalk on 3 June 1965. However, from this point on, American performance in manned spaceflight would consistently outstrip Soviet performance up to the lunar landings.

Between March 1965 and November 1966, ten Gemini flights took place. While the United States set one space record after another, no cosmonauts orbited the Earth. In October of 1965, *Gemini VI* rendezvoused with *Gemini VII*, with the crew of *Gemini VII* spending two weeks in Earth orbit. The first successful docking of two spacecraft occurred during *Gemini VIII*, which was crewed by Neil Armstrong and David Scott. The final flight of the program, *Gemini XII*, solved many problems inherent to spacewalking and helped to refine flying techniques as well as spacesuit technology. With the conclusion of Project Gemini, spaceflight had become operational if not routine, and many of the skills needed for Apollo had been honed to sharp accuracy.

Although Project Gemini had seen some close calls in space, NASA's first major catastrophe occurred on the ground. On 27 January 1967, during a routine ground test at the Kennedy Space Center, the Apollo One command module burst into flames and the three crew members, Gus Grissom, Ed White, and Roger Chaffee, perished through asphyxiation. Investigations showed that while faulty wiring was the immediate cause of the fire, neither NASA nor the contractor North American Aviation had fully understood the need for all components to work together in a complex system. Many at NASA and at North American Aviation believed that the fire gave them

Space shuttle liftoff from the Kennedy Space Center, Merritt Island, Florida. State Library and Archives of Florida.

a new awareness of possible problems and actually facilitated the success of Apollo. The tragedy shook public confidence in Apollo, but, inspired by the memory of John F. Kennedy, Americans continued to support the program.

With many changes now built into the Apollo spacecraft, *Apollo 7*, a test of the command and service module in Earth orbit was launched on 11 October 1968. *Apollo 8*, launched on a Saturn V on 21 December of the same year, successfully circumnavigated the moon with the command and service modules, albeit after the USSR had managed to orbit the moon with an unmanned spacecraft, *Zond 5*. Satellite photos revealed that the Soviet moon rocket, the N-1, might soon be ready to take men to the moon. Project Apollo culminated in the *Apollo 11* mission, launched on 16 July 1969, with commander Neil Armstrong, lunar module pilot Buzz Aldrin, and command module pilot Michael Collins. Two weeks before the launch, a Soviet N-1 moon rocket blew up on its launch pad, effectively ending the moon race. Armstrong and Aldrin touched down on the moon on 20 July 1969, with a television audience of approximately a billion people. Backed by many thousands of workers, managers, and engineering specialists, Armstrong, Aldrin, and Collins met Kennedy's goal and fulfilled the age-old dream.

With Apollo now fully operational, the focus of the program shifted to scientific lunar exploration.

With the exception of *Apollo 13*, subsequent missions made significant discoveries regarding the geological composition and history of the moon using new equipment, such as the lunar rover. The final Apollo mission, *Apollo 17*, splashed down on 19 December 1972. The crew had taken the first photograph of the full Earth from space, underscoring the planet's fragility and interconnectedness.

In retrospect, it is not surprising that the Americans reached the moon before the Soviets, despite early Soviet success. The death of Sergei Korolev in 1966 sealed the fate of a Soviet moon program that was underfunded and subject to corruption, with resources spread too thinly over many design bureaus. The result was less equipment, fewer tests, and weaker technology. The American space program had the benefit of a thriving economy, largely due to its position after World War II, which was much stronger than that of the Soviet Union. Government and private enterprise formed strong partnerships in the United States that benefited the space program through NASA's practice of awarding contracts to aerospace companies who would then build space hardware. Ironically, the democratic-capitalist United States government had better command of its space resources than the totalitarian USSR.

Beyond the Moon

Mars exploration has been prominent in the space programs of the Soviet Union (and later Russia), the United States, Europe, and Japan, with numerous missions and robotic spacecraft having been launched toward or directly at Mars since the 1960s. Mercury has been visited by the *Mariner 10* and MESSENGER missions, the former in 1975, while the latter made a flyby in January 2008. A third mission is due to arrive in 2020. Similar to Mars, Venus has had many missions sent to it; the first was the American *Mariner 2* craft in 1962, but most have been from Soviet Venera craft. Exploration of Jupiter has been undertaken since 1973 by a series of NASA's automated spacecraft, most of them, apart from the orbiting Galileo craft, have been flybys. Saturn too

has been explored only through unmanned NASA visits, including flybys by *Pioneer 11* (1979), *Voyager 1* (1980), *Voyager 2* (1982), and the Cassini mission which entered orbit in 2004 and is likely to run into 2010. Uranus has only been explored through *Voyager 2*, with the closest approach coming in January 1986. Similarly, the sole visit to Neptune was the flyby of *Voyager 2* in 1989.

After the Space Race

With the winning of the space race and the advent of détente, America's political will to support large-scale space initiatives dissolved. The Skylab temporary space station project of the 1970s utilized leftover Saturn V rockets and increased knowledge of living and working in space. The Apollo-Soyuz test project of 1975, in which Apollo and Soviet Soyuz spacecraft rendezvoused and docked in the Earth's orbit, marked the first major cooperative venture in space.

During the late 1970s, NASA completed the development of the space shuttle program. Originally intended to serve as a taxi with routine flights to and from a permanent orbital space station, the shuttle instead stood on its own because of NASA's reduced budget. A private company built the shuttle fleet, which had its maiden voyage with the shuttle *Columbia* launching on 12 April 1981. During nearly three decades in service, space shuttles have deployed military satellites, housed numerous science experiments, carried the Hubble space telescope into space, and helped build the International Space Station (ISS). Yet the two major disasters of the Shuttle program, the *Challenger* explosion on 28 January 1986, and the disintegration of *Columbia* during reentry on 1 February 2003, underscored the problems of constant, routine access to space that had plagued the shuttle program since its inception. In both cases, experts blamed the nature of NASA bureaucracy, which had become increasingly inflexible since the days of Apollo.

The Soviet policy of glasnost (openness) initiated under Premier Mikhail Gorbachev (b. 1931) meant that the successes and failures of the Soviet space program could be discussed openly. This policy certainly

helped the success of the Mir space station (1986–2001), the world's first long-term orbital structure for living and working in space. Assembled with updated versions of the *Soyuz* spacecraft, the station proved the feasibility of long-term space habitation, hosting several American crews during its tenure. The fall of the USSR in 1989, although difficult on the Russian program, opened up new commercial opportunities for spaceflight in Russia.

International Cooperation in Space

Since the end of the superpower space race, many other nations have begun to participate in the arena of space exploration. Major European nations joined the European Space Agency in 1980. The agency has contributed key satellites and scientific instruments to Russian, American, and joint endeavors. Additionally, the agency has produced many launchers for commercial use. Groups in Japan, including the National Space Development Agency (NASDA) have also begun to make strides into space with sophisticated technology. The Chinese space program, while younger than and not as versatile as the European and Japanese programs did succeed in putting a man into space on 15 October 2003.

The construction of the International Space Station (ISS) began in 1994. Although NASA has overall responsibility for the project, major components have been built by Russia, ESA, and NASDA. The station has been widely criticized for cost overruns and delays that have consumed much of the NASA budget. However, the station has hosted important research, particularly in the area of pharmaceuticals, and has provided humans with a permanent place to live and work in space.

The Future of Space Exploration

Two major themes currently dominate much of the discourse surrounding space exploration: the possibility of a manned mission to Mars and the widespread privatization and democratization of space travel. For years space enthusiasts of many stripes have been

lobbying for a manned mission to Mars. However, without major political impetus, such as the need to upstage the Russians in the Cold War, American leaders have seen little reason to fund such an expedition, and countries other than the United States do not have the resources for such a mission in the near future. President George W. Bush (b. 1946, in office 2001–2009) announced plans for a permanent lunar base with a Mars landing in the next twenty years, but even with careful budgeting, this will be difficult to complete without a strong national commitment. In 2010, at the beginning of the second year of President Barack Obama's administration, rumors that U.S. plans for future human spaceflights would abandoned were met with harsh criticisms (especially from NASA) until he renewed the goals, which included a Mars landing by 2030.

The flight of the first privately funded spacecraft, SpaceShipOne, designed by the U.S. aerospace engineer Burt Rutan (b. 1943), on 21 June 2004, inspired many entrepreneurs who wish to expand the opportunities for human spaceflight. Using SpaceShipTwo, a reusable sub-orbital spaceplane, Virgin Galactic aims to be taking tourists into space by 2010. Other privateers include Bigelow Aerospace, which has launched two space station modules—*Genesis I and II*—and plans to build an orbiting hotel in space. SpaceX's *Falcon 1*, a liquid-propelled orbital launch vehicle has undertaken two successful flights; *Falcon 9* is scheduled to launch in May 2010. To a certain extent the Google Lunar X-Prize has served to hasten private space exploration through the announcement of a \$20 million prize for the first privately funded mission to the moon. But so has the general desire for space exploration and the need to be the first.

Existing space technology is extremely expensive and space travel is dangerous. These factors currently inhibit space exploration from being immediately profitable and accessible to all. Yet, if you have enough money the Russian space program has been willing to take paying passengers into space. But if dedicated scientists and engineers continue to pursue solutions to the problems of propulsion, spacecraft control, and long-term human survival in space, the

possibility of space exploration for all—both in the Earth's orbit and in interplanetary space—will come closer to our grasp.

Spanish Empire

The Spanish Empire forms a crucial component of any understanding of world history during the first global age (c. 1400–1800 CE). At its height, it extended around the world; the activities of its officials and subjects, many of whom never set foot in Europe, established and maintained a significant number of the period’s economic, political/military, and cultural networks, and its territories produced some of the most desirable products of global commerce.

The concept of a “Spanish Empire” has become increasingly controversial. Spain as an entity never existed during the first global age in the sense of a political unit that directed an overseas empire, created and retained for the benefit of the metropolitan center. Instead, before the early nineteenth century, a territorially huge, composite monarchy tied together under the rule of a single dynasty a variety of domains, which included the Crown of Portugal between 1580 and 1640. The accession of a new monarch, Charles IV (1748–1819), was still marked in Manila when the news finally arrived in 1790 with cheers of “Castile, Castile,” and leaders of a newly constituted country of Spain only decided in 1837 to govern its remaining overseas territories by special laws.

Historiographical Controversies

Two types of ideological position drive most of the really contentious debates about the history of this composite monarchy. First, a large number of contemporary countries have originated entirely or in part with the independence of its domains, and the resulting nationalistic historiographies, including that

of the modern country of Spain, embody understandings of it as putative empire. From their differing local perspectives, historians of each of the resulting nations pictured the empire in a manner that justified costly independence wars and explained serious nineteenth-century economic and political problems. Second, in order to construct a tidy narrative for a geographically messy subject, some historians present “Spain” in the first global age as a developing, centralized state, whose strength at any time was determined by its autonomy in formulating policy and its capacity to shape society, while others challenge this vision as a useful way to understand this monarchy’s history.

The royal cosmographer Juan Bautista Muñoz (1745–1799) convinced the Crown to establish in 1781 the magnificent Archive of the Indies in Seville to preserve the record of the administration of the Hispanic monarchy’s vast Castilian domains. In part because of this resource, historians have concentrated heavily on the monarchy’s administrative networks involving the interactions among various court officials and councils and the royal viceroys, governors, high commissioners, judicial tribunals and justices, trade and taxation officials, and major municipal councils. The emphasis on administrative interactions produces a picture of a system much more unitary and under the control of royal authority than was ever true. A different impression emerges when greater attention is devoted to connections between locations that involved lineage networks, the regular orders or church administration, the investors, managers, and workers (slave and free) who developed agricultural and mineral resources, the merchants who organized vast commercial networks in the face of incredible obstacles, and the massive

A Spanish traveler carved this message in a canyon wall in central New Mexico in 1709.

world of fraud and clandestine networks of production and smuggling. The roles of women have only been made somewhat visible in the last few decades. In general terms, research on the domains of other Iberian Crown governments remains more poorly developed than that on Castile.

The Domains of the Hispanic Monarchy

The traditional chronological limits for the history of this composite monarchy are the marriage in 1469 of two first cousins, the “Catholic monarchs” Ferdinand and Isabella of Trastámara, and the defeat at Ayacucho (modern Peru) of the last Bourbon army in the continental Americas on 9 December 1824. In between, the territorial extent of the monarchy’s realms varied a great deal, and events continuously influenced the patterns of interactions among its domains and at times could inflect them significantly. Isabella (1451–1504) inherited the crown of Castile, which already included the Canary Islands, on her brother’s death in 1474, and Ferdinand (1452–1516) obtained the crown of Aragón when his father died in 1479. The Crown of Aragón was a composite monarchy consisting of the kingdoms of Aragón and Valencia and the principality of Catalonia in the Iberian Peninsula, the counties of Cerdanya and Rosselló north of the Pyrenees, and the island kingdoms of Majorca, Sardinia, and Sicily. After a

decade of fighting, the Muslim emirate of Granada surrendered on 2 January 1492 and became a Castilian domain. Ferdinand added the kingdom of Naples to the Aragonese domains when the ruling Trastámara branch died out in 1504, and in 1512, he conquered the Iberian kingdom of Navarre, which he added in 1515 to the Crown of Castile. By this time, Castile’s domains had expanded significantly in the Caribbean region as a result of the four expeditions of Christopher Columbus (1451–1506) and those of adventurers drawn to the region in search of wealth.

Isabella’s death brought to the Castilian throne her daughter Joanna (1479–1555) and Joanna’s husband Philip of Habsburg (1478–1506), son of the Holy Roman Emperor Maximilian I (1459–1519) and ruler of the Low Countries and the Franche-Comté on the west bank of the Rhine. Due to Joanna’s signs of mental illness and the growing political instability after death removed Ferdinand as Aragonese ruler and Joanna’s regent in Castile, her elder son with Philip, Charles of Habsburg (1500–1558) became joint ruler of the Iberian Crowns. When his grandfather died, Charles was elected Holy Roman Emperor as Charles V, which united the destinies of the Crowns of Aragón and Castile, the realms of the Habsburg Rhine and Low Countries, and the dynasty’s holdings in Central Europe, although the latter would eventually be ceded to Charles’s younger brother Ferdinand.

The central square with cathedral and government buildings of Spanish design in Guanajuato, Mexico, is representative of changes to indigenous architecture after the Spanish conquest.

Expansion During the Reign of Charles V

Charles's Castilian territory expanded enormously with the defeat of the Aztecs in 1521, the beginning of Inca subjugation in 1532, and a series of long voyages intended to turn the vast Pacific Ocean into a Castilian zone from the Americas to the Philippine Islands. Regions of the viceroyalties of New Spain, with its capital at Mexico City, and Lima would eventually produce about 80 percent of the world's silver, for which demand was particularly high in China and South Asia. After the death of the Milanese ruler Francesco Sforza, Charles gained a major financial and production center when he took control of the Duchy of Milan, and he continued the efforts, begun in 1497 with the conquest of Melilla, to add North African enclaves.

The terrible destruction of American peoples by epidemic diseases, war, the collapse of complex economic and political regimes, and harsh conditions of forced labor motivated the Dominican friar Bartolomé de Las Casas (1474–1566) and other Iberian authors to develop sophisticated ideas about economic policy, constitutional thought, human rights, and international relations. These would provide an important intellectual context for the eighteenth-century

development of distinctive American identities and of the Liberal constitutionalist movements that would do much to reshape world political history in the second global age.

Revolt, Expansion, and Rivalry

Subsequent developments within the global monarchy were shaped in fundamental ways during the reign of Charles's son Philip II (1527–1598) by the revolt that began in the late 1560s in his Low Countries domains, the organization of Manila in the Philippine Islands as a connecting point between American silver production and the enormous Chinese appetite for this product, and by Philip's successful assertion in 1580 of his claim through his mother to the throne of Portugal, as Philip I. From the Dutch rebellion and resulting eighty years of military conflict to 1648, the United Provinces of the Netherlands emerged as a potent commercial and political opponent, and by the mid-seventeenth century, Amsterdam had become the financial center of European activity in the world economy. The emergence from 1571 of regular commercial interactions between Acapulco and Manila gave the Castilian government broader interests in the vast Pacific region and produced significant flows of Chinese immigrants, merchants, and products toward

Hernán Cortés, conqueror of the Aztec Empire, secured large parts of Mexico for the King of Castile.

the Philippines. The crown of Portugal brought with it not only rule over Castile's neighboring Iberian kingdom but even more significantly, over Portugal's extensive non-European domains.

The European and Mediterranean wars of Charles V and Philip II placed great pressure on the Habsburg dynasty's financial resources. The long, fragile commercial links among Hispanic global domains and the monarchy's role as the military bastion of reformed Roman Catholicism made Castilian and Portuguese positions in the global economy attractive targets for intervention and attack by the Dutch, English, and French Protestants. During the reigns of Philip's son and grandson, Philip III (1578–1621) and Philip IV (1605–1665), matters deteriorated further. The Dutch East India Company (Verenigde Oost-Indische Compagnie, or VOC) used methods similar to those of the Portuguese to secure important chunks of the European share of Indian Ocean and East Asian commerce, and other Dutch commercial interests asserted increasing control over another significant component of the global economy, the Atlantic slave trade. Moreover, the Dutch took over the sugar-producing

regions of northeastern Brazil and gained footholds in the Caribbean and North America. English and French groups also became more active on a global scale in the wake of such dramatic Dutch successes. The contraband trade, always important from the beginning of the global economy, increased notably everywhere as merchants and officials sought to avoid arbitrary royal seizures of bullion and other goods and a Crown fiscal and monetary regime oriented exclusively toward military commitments too extensive for the Hispanic monarchy to fulfill.

In addition to the Dutch war, the monarchy found itself embroiled with the revived French monarchy under the Bourbon dynasty in contests that would eventually cost it the Aragonese domains north of the Pyrenees, the Franche-Comté, and some territory in the southern Low Countries. European conflict focused, however, on the terrible Thirty Years War (1618–1648), which centered on the Holy Roman Empire, whose Habsburg emperors were the cousins of the Hispanic rulers. Faced with weakened elite support, riots, evasion, and fraud everywhere, the government of Philip IV's favorite, the Count-Duke of Olivares (1587–1645), pulled ever more administrative functions toward Crown institutions and officials in Madrid, further alienating those elsewhere and making it increasingly difficult to achieve royal aims in the face of widespread disobedience. The most damaging manifestations of discontent surfaced in 1640 when the Iberian Habsburg dynasty was confronted with rebellions in Catalonia, which it would only recover in 1653, and Portugal, whose independence under rule by the Braganza dynasty would be conceded in 1668 when Philip IV had been succeeded by a sickly infant who reigned as Charles II (1661–1700).

Bourbon Dynasty and American Independence

When Charles II finally died without direct heir, a genuinely global war began, to decide whether the Hispanic monarchy would be ruled by a member of the Austrian branch of the house of Habsburg or of

the French Bourbon dynasty headed by king Louis XIV (1638–1715). The long War of the Spanish Succession was finally ended by the Treaty of Utrecht in 1713, which awarded the throne to Philip V (1683–1746) of Bourbon, Louis XIV’s grandson, but stripped away control of the southern Low Countries and the Italian domains, except Sardinia (Naples and Sicily would later be recovered by the dynasty). For more than a century, Creole elites in the Americas and Philippines gained greater control and influence over royal and church offices and institutions, often in violation of existing statutes, and especially after the monarchy’s difficulties during two major world wars of the mid-eighteenth century (1740–1748 and 1756–1763), in the latter of which the British captured Havana and Manila in 1762. Bourbon ministers felt that these domains required greater supervision and that their economies needed to be transformed in order to produce more revenue for their defense.

Wealthy Creoles were squeezed out of Crown administrative positions by peninsular appointees, excise taxes were levied on widely consumed products, and labor controls over indigenous peoples were challenged in order to bring them into a money economy in which their purchases could be taxed. Rather than play its traditional role of assisting Creole elites to maintain their disproportionate share of

production and political authority, the Crown was increasingly seen by many of them as an arbitrary, destabilizing entity, especially after significant uprisings of Native Americans, urban plebeians, and African slaves appeared to confirm Creole claims that Bourbon policies placed control by the “civilized” minority in jeopardy. British maritime successes during conflicts with revolutionary France exposed the weak connections between Madrid and the monarchy’s overseas domains. Napoleon’s imposition in 1808 of his brother as Spain’s ruler occasioned independence uprisings in the Americas, and the restored Bourbon monarch Ferdinand VII (1784–1833) faced too much postwar poverty and political turmoil in his peninsular domains to hang on to more than Cuba, Puerto Rico, and the Philippines.

Research Challenges

Although the legal and administrative regimes of the various Hispanic domains influenced the histories of each, economic, religious, subaltern, and clandestine interactions created alternative stories every bit as decisive in forming the complex reality of such a vast territorial conglomerate as the Hispanic monarchy. In the end, the histories of each place were fundamentally shaped by their shifting relationships with other

constantly changing locations, and until researchers develop the means to integrate such multivariate and multidimensional interactive webs, we will not approach an adequate grasp of the processes driving the history of this monarchy or the world within which it was deeply integrated during the first global age.

Spices

Trade in spices—especially peppercorns, cinnamon, and cloves—brought together diverse cultures of the western, southern, and eastern parts of the world. This exchange of spices stimulated the first global age (c. 1400–1800), and the beginnings of economic globalization, wherein actions in one area of the world greatly affected people and events on another, far-off continent.

What are spices? A spice is usually defined as an aromatic part of a tropical plant, be it root, bark, flower, or seed. All spices, with the exception of vanilla, chili pepper, and allspice, are of Asian origin. Many people group herbs and spices together as one set of plants. Herbs are quite different. An herb is a plant that does not have a woody stem and dies at the end of each growing season. Most herbs derive their flavoring or medicinal uses from their leaves.

All spices played a role in world history, but the spices that had the most effect on global trade and cultural interactions were chili peppers, black pepper, cinnamon, cloves, and nutmeg.

Spices in the Ancient World

In the ancient world spice trading across the Indian Ocean and east to present day Indonesia and north to China was a daily occurrence. The Western world knew little of spices, and what they did know was filled with imaginative tall tales of birds building nests with cinnamon, and inhabitants of “clove island,” (Ternate, Tidore, Moti, Makian, and Bacan islands of Indonesia, the ancient capitals of clove cultivation) never growing old. The Asian trade was

driven by the monsoon winds that blew ships south and west in the winter, and north and east in the summer. For centuries the West knew little of the spices that flowed east and west through Asia.

For China, records from the Han dynasty in the second century BCE indicate knowledge of a plant called *Piper nigrum*, which was supposed to be from the west of China, but more likely came from India, where black pepper originated in the southwest on the Malabar Coast. Also in the Han dynasty cinnamon first entered Chinese records as coming from present-day Vietnam. Cloves came out of the Moluccas and both the Chinese and Indians were active in the clove trade. Cloves appeared in India in the Ramayana literary classic somewhere around the beginning of the common era. Cloves—considered to be a breath freshener to be used in China before meeting with the Han emperor—were named “chicken-tongue fragrance.”

In the West the Romans were the first to use the spices of the East. Traders and middlemen carried black pepper from India up through the Red Sea and into Egypt and then across the Mediterranean Sea. Spice also flowed into Europe from the Middle East as Rome extended its empire in that direction. The Romans favored black pepper as their mainstay cooking spice, while cloves were mostly used in incense and perfume.

Spices in the Medieval World

The medieval world and spices were shaped by several events. The first was the decline of the Roman Empire by 500 CE and the loss of their spice-trading networks. The second was the birth of Muhammad

Pietro Longhi, *The Spice-Vendor's Shop* (1752). Oil on canvas. Galleria dell'Accademia, Florence.

in 570 CE and the rapid rise of Islam, which had spread north to southern Spain and east to Malay Peninsula by the year 1000 CE. Finally, by the beginning of the eleventh century, the Roman Catholic Church had grown in size and power and was seeking to expand its influence. The combination of these events led to the rise of Islamic influence in controlling the trading routes of both the Arabian Peninsula and the East Indies while the Catholic Church organized the crusades to recapture the Holy Land from Islam.

While the crusades brought cohesion among some peoples in western Europe, the cross-cultural experiences of the western crusaders in the Middle East changed their views of food and how food is prepared and eaten. Spices such as pepper, nutmeg, cloves, and cardamom entered the diet of the crusaders, as did figs, dates, lemons, and oranges—causing a revolution in the staid tastes of the West.

Once the spices of the Eastern world had been experienced the Italian port cities of Venice and Genoa set themselves up as the conduit to bring the spices of the East into the West. Europe was changing its

tastes but the Arab and Muslim worlds of the East controlled access to spices.

Spices in the Age of Exploration

The “Age of Exploration,” a Western/European expression, involved the nations of coastal/continental Europe and the British Isles. From the late fifteenth century Portugal, Spain, the Netherlands, England, and, to a lesser degree, France and Denmark, competed for the market in spices in two areas of the world, South Asia and Southeast Asia. As these nations competed, this quest for spices led to the first “global” wars.

It all began with Portugal and Vasco da Gama in 1498 when this Portuguese navigator arrived at Calicut on the Malabar Coast of west India looking for black pepper. After miscommunications with the Hindu ruler and other difficulties, Vasco da Gama sailed home with a shipload of pepper. One of the things that he learned was that the network of Arab, Muslim, and Persian merchants who controlled the flow of spices would have to be broken. The Portuguese continued to come to India after 1500 and soon set up bases and shipbuilding facilities at places such as Goa. Between 1503 and 1540 Portugal supplied Europe with most of its pepper but was never able to break the spice trade monopolies that existed. For the rest of the sixteenth century the Portuguese moved to the east to acquire other spices such as cinnamon, nutmeg, and cloves. Their empire expanded but their share of the spice market was very small.

In the 1590s the Dutch entered the spice competition returning from Asia with a modest shipload of pepper. By 1601, a large fleet was assembled and the Dutch solidified their efforts by forming the Dutch East India Company (Verenigde Oost-Indische Compagnie, or VOC) and focused their efforts on ousting the Portuguese. They were successful throughout the seventeenth century capturing the Spice Islands with their nutmeg and cloves, and then controlling the Straits of Malacca. Eventually Ceylon (modern-day

Sri Lanka), and its cinnamon trade, fell into Dutch hands. One Dutch ditty of the day exclaimed:

Wherever profit leads us,
To every sea and shore,
For love of gain,
The wide world's harbors we explore.

These verses did not tell the whole story of what competition wrought, not only for the competitions between the Portuguese, Dutch, English, Spanish and French, but for cross-cultural relations with the inhabitants of the spice-producing areas. Bloody encounters, to acquire spices as well as to expand networks for profit, were often the rule. Felipe Fernandez-Armesto, in his book *Pathfinders* (2006, 205), sums up the European-native encounters: “They began with embraces, continued with abuse, and ended in bloodshed.”

Spices in the Age of Industrialization

By the nineteenth century the Dutch had settled into maintaining their spice empire in the East Indies. Markets were established and maintained. The British controlled this empire for a short time during the Napoleonic Wars, but gave that up to focus on South Asia. The French were able to transplant cloves successfully from the East Indies to East Africa, which led to an extensive system of slavery that persisted until late in the nineteenth century.

In the early 1800s a new area of the world entered the spice trade. It all began in the northeastern United States at the port of Salem, Massachusetts. An enterprising sea captain named Jonathan Carnes set out on a voyage to the East Indies in the 1790s. After two trips he returned to Salem with a boatload of black pepper which reaped a profit of 700 per cent. The competition was on. Other Salem ships sailed back and forth to Sumatra to acquire pepper. Historical accounts tell of their adventures in the waters south of the Straits of Malacca. There were many encounters with the Malay natives and their wavy lethal daggers, known as *creese*.

Meteor-brand spice tin from the 1930s, produced in Lebanon, Missouri. Photo by Todd Franklin.

In the late nineteenth-century advances in technology such as steam power led to the development of ships that were able to crisscross the globe with more speed and efficiency. Entrepreneurs such as Thomas Cook established travel agencies to take citizens on global tours. Speed of travel not only got spices moving more quickly to their markets but also brought people into contact with the source of spices and how they were used in cooking. The British control of South Asia in this period and the influences of Indian cooking on British society are still strong today in curry and other dishes.

The Twentieth Century and Beyond

In our modern era the spice trade has become a very settled business. The Dutch continued to control certain aspects of the trade out of the East Indies until the Indonesian revolution, but the overland Chinese, Malay, and other ethnic groups of South and Southeast Asia continued their networks as if the Europeans

had never come east. During the twentieth century many spice companies emerged in Europe and in the Americas. Each had their own network of suppliers from India or Southeast Asia.

In the late twentieth century, one U.S. spice company, McCormick, which was founded late in the nineteenth century in Baltimore, Maryland, began to emerge as a major global spice company. The secret of their success was the fact that they sent company employees to the source of the spices they needed and then set up their own bases and networks. Not only did McCormick set up networks, they established operations at various sources of global spices to both control the gathering of spices and insure their quality. Today McCormick controls many of the European spice companies, although these companies maintain their traditional names.

The use of spices has changed significantly in the last half-century. Prior to that time people bought individual spices to flavor their home-cooked meals. In recent decades the great majority of the spices that are purchased are used by large multinational food companies in the preparation of processed foods that are sold in global supermarkets.

Spices are now an integral part of many global cuisines and many of these dishes, flavored with spices such as the chili pepper, have traveled around the world and found a place in the eating habits of multiple cultures. One can now find restaurants on all

continents that offer dishes that blend the spice flavors of different cultures, cuisines, and traditions in new and exciting culinary spice explorations.

Sports

The modern concept of sport refers mainly to organized and competitive physical activities such as cricket, basketball, table tennis, golf, or soccer and excludes recreational activities such as walking or hunting. Thus it leaves out games such as bridge, chess, or poker. This broad definition of sport reflects the universal human passion for movement.

Sporting activity is grounded in human physiology and a love of movement that all humans share at birth and embrace throughout life. This is demonstrated by the popularity of such recreational pursuits as walking and swimming, and by a wide variety of physical pastimes, such as hunting, fishing, skating, skiing, and sailing. The word *sport* derives from the Middle English word *disport* meaning to frolic, play, or amuse oneself. In modern usage, however, sport includes the elements of competition, physical prowess, and rules. In this sense sport mainly refers to organized activities such as cricket, basketball, or soccer and excludes recreational activities such as walking or hunting. It also leaves out games such as bridge, chess, or poker. A broad definition of sport includes recreational activities and games, but a narrower definition limits sport to athletics of a competitive nature.

It is helpful to think of sports as a form of cultural expression that reflects a culture's history and character. As with other performed forms of cultural expression, sports appeal to the emotions and to aesthetics. Moreover, as with all arts, larger issues of a society involving economics, politics, technology, religion, architecture, and social questions can be observed in the circumstances of sports. As the social historian

Jacques Barzun observed about the United States in 1954, "Whoever wants to know the heart and mind of America had better learn baseball, the rules and realities of the game—and do it by watching first some high school or small town teams" (Barzun 1954, 159). The sports sociologist D. Stanley Eitzen has updated this observation: "Baseball, then, represents what we were—an inner-directed, rural, individualistic society. It continues to be popular because of our longing for the peaceful past" (Eitzen 1996, 23).

There is no evidence that sports are necessary for human existence. Although a particular sporting contest might enflame passions and spark a riot, there are no instances of sports starting or ending wars. Two world wars, a cold war, and numerous regional conflicts, for instance, have occurred during the time of the modern Olympic Games. Sports do not drive the economies of the world, nor do they determine foreign policy, and there is no quantifiable evidence that they are necessary in schools. There exists much anecdotal testimony, however, about the usefulness of the arts, including sports, for creating multidimensional, interesting individuals. Athletic events, for example, prompt conversations that cut through all divisions of society, and sports metaphors sprinkle the language: "on target," "level playing field," "sticky wicket," "throw in the towel." Sports are a universal phenomenon that can be found with all peoples and in all times, and they invite cross-cultural comparisons to help ascertain what it means to be human.

Influences on Sports

Geography, vocation, religion, entertainment, Eros, and warfare have all influenced sports. It is easy to

Sports and music have become the universal languages. • Philip H. Knight (b. 1938)

see the general influence of geography: people in cold climates invented skiing and ice skating, for example, and those bordering water were interested in boating and swimming. Hot, desert climates cautioned against excessive exposure of the body. As far back as the fifth century BCE, the Greek historian Herodotus noted that people in the Middle East kept themselves covered and thought nudity was shameful. It should be noted, however, that ancient Egyptians of the Nile Valley wrestled nude, or while wearing a light loincloth. On a local level, geography involves the location of stadiums or sports venues and their influence on people's lives. Ancient Greeks valued their *gymnasion* for physical and intellectual stimulation, for example, and modern U.S. universities make room for stadiums on their campuses.

Vocation has inspired sports such as the rodeo, in which cowboys show off their skills at roping, branding, and bronco busting. Religion was significant in the ball games of the Maya and the bull jumping of the Minoans, and has been a source of inspiration for modern athletes. Sports for entertainment can be seen in the crowd scenes in the temple carvings at Nineveh, in the friezes of ancient Egypt, and in the contemporary phenomenon of ESPN, a television channel dedicated to twenty-four-hour sports

broadcasts. More evidence can be seen in the ruins of Greek and Roman hippodromes, built for chariot races; and the ruins of Roman arenas, built for gladiator fights. These are comparable to the new stadiums U.S. cities build in order to attract "big league" sports teams.

The erotic nature of sports has been a taboo subject, but is explicit in the art of ancient Greece, particularly on the trade pottery decorated with active, naked athletes. Ancient Egyptians painted nude acrobats and athletes on their tomb walls. Modern sports such as figure skating, gymnastics, swimming, diving, and body building, all of which expose the human body, possess an unspoken but obvious erotic aspect.

The most important inspiration for sports, however, has been warfare. In the ancient Olympic Games (776 BCE–393 CE) most of the skills tested by the events had fighting applications. Javelin throwing was one of the most apparent, but the contestants also ran, jumped, boxed, wrestled, threw a discus, raced chariots, and rode horses. One of the most popular events was the *pankration*, a combination of wrestling and boxing with almost no holds barred. The two combatants fought until someone surrendered. In 564 BCE Arachion, a pankrationist, while being strangled in a

In the late twentieth century basketball became one of the most popular sports around the world. Here, young men in Shanghai, China, play in a basketball tournament (2003).

If you must play, decide on three things at the start: the rules of the game, the stakes, and the quitting time. • Chinese Proverb

bout, won by dislocating his opponent's toe. Arrachion died, but the judges crowned his corpse with the olive wreath of victory. The final event of the ancient games was a running race in which the men wore armor and carried a shield, a concluding tribute to the importance of warfare in sports.

The influence of combat can also be seen in Native American contests. Eastern Woodlands Indians played a ball game that was the prototype of lacrosse. The artist George Catlin (1796–1872) observed a Choctaw match in the 1830s in which some six to seven hundred players tried to throw a small ball through goals placed approximately 250 meters apart. They used a meter-long stick with a netted hoop on the end to catch and hurl the ball without touching it. There was a great deal of running, yelling, hitting in the face and shins, and fighting until a hundred goals were scored. Afterward the winners claimed their wagers, everyone took a drink of whiskey, and the Indians returned home. They called their game *baggataway*, which translated into “little brother of war.”

Sports in the Premodern World

During the years of the Middle Ages in Europe (500–1500), the upper class sponsored tournaments to keep sharp the fighting skills of the knights, while the lower classes practiced archery. For pastimes, the elite hunted on horseback with falcons and played shuffleboard in their castles, while the peasants pursued crude games of football between villages, as well as bowling, field hockey, and games of quoits in the stables. Archery was a sport for the yeomanry of England and a passionate activity for the urban bourgeoisie of western Europe.

Marco Polo, traveling in Asia, recorded a large, month-long hunting expedition by Khubilai Khan in 1275 that included members of the court, family, and administrative officers using elephants, hunting dogs, horses, and ten thousand falconers to capture herons, swans, storks, and other game. The elite also played a form of polo, a horse game known from the Middle East to the Far East. Chinese court women played astride donkeys or ponies. Other Chinese,

This Japanese woodcut from 1877 shows a British-style polo match. By Utagawa Hiroshige.

both men and women, played *cuju*, a game like soccer that utilized a ball stuffed with hair, and also enjoyed a game reminiscent of the present-day sport footbag (often called Hacky sack, after one manufacturer's brand of footbag): people in a circle tried to kick a small deerskin ball in the air. People in Asia, moreover, practiced varieties of martial arts for personal discipline and defense after the invention of martial arts in the sixth century. Sports in precolonial sub-Saharan Africa are less well known, but there are examples of canoe races and, of course, wrestling, a sport that seems to have been universal throughout Africa.

Modern Sports

Modern sports evolved mainly in the West during the time of the industrial and scientific revolutions, and the demographic surge of population from the countryside to the city. The British sociologists Norbert Elias and Eric Dunning and the U.S. historian Allen Guttman have analyzed the differences between pre-modern and modern sports that accompanied this major societal shift. Elias and Dunning developed a theory about a "civilizing process" whereby people learned to control emotion and aggression in sports to reduce injury. Examples of the civilizing process include the adoption of gloves in boxing. Guttman

developed a list of distinguishing characteristics of modern sport: secularism, equality (equal rules for all participants), bureaucratization (organizational control), specialization (specific positions and roles played in a game), rationalization (rules and training for efficient skills), quantification (an emphasis upon measurement by numbers), and record keeping. Other historians have added the use of publicity and public announcements to the list. This definition of modern sports is widely accepted by sports historians. The process of adopting these characteristics is sometimes called "sportification."

Western sports spread globally as a result of individual enthusiasm, Christian missionary work, sports organizations, military occupation, and the Olympic Games. Soccer, the world's most popular sport, began as a game in British boys' schools in the mid-nineteenth century. It spread to Europe, Africa, and South America through transplanted British schoolmasters, traveling students, interested businessmen, posted soldiers, and visiting sailors. Soccer and cricket, another British sport, spread throughout the British Empire, supported by the colonial administrations and by the British army, which used sports to forestall boredom and promote physical conditioning.

In some cases, enthusiasts helped spread sports. This was the case with baseball, as when A. G.

A Native American pictograph depicts a wrestling match.

Spalding (1850–1915), a professional baseball player and later manager and eventually president of a baseball team, sent teams abroad to promote the sport. The Marylebone Cricket Club, the arbiter of cricket, dispatched touring teams to Australia that eventually resulted in a biannual international match called the Ashes.

Christian missionaries inspired by “muscular Christianity,” a pedagogy that combined sports and religion to produce moral people, also took Western sports into Africa and Asia. The muscular Christian mentality helped to spread the sports of table tennis, tennis, track and field, soccer, and basketball. Most significant of these missionary organizations was the nonsectarian Young Men’s Christian Organization (YMCA), an organization founded in London in 1844 that was particularly active from 1850 to 1920. It established branch associations in cities around the world that promoted Christianity and athletics. It commonly constructed pools to teach swimming and gymnasiums to teach basketball and volleyball, games invented by YMCA instructors. James Naismith (1861–1939) put together, tested, and refined the rules of basketball in 1891; the game was not only popular in the YMCA, but also in school systems. In terms of numbers of participants and fans, basketball, along with soccer, became one of the most widespread sports in the world.

Because of the lack of comparable statistics it is difficult to measure the most popular modern sports, but in terms of the quantity of national sports organizations dedicated to a particular sport, the leaders are soccer, basketball, tennis, track and field, and volleyball. To a lesser extent American football, cricket, baseball, rugby, skiing, boxing, judo, car racing, cycling, swimming, and table tennis can be included. From that list a bias toward sports that originated in the West is evident. A major exception is judo, which was synthesized by Jigoro Kano in Japan from several schools of unarmed combat in the last part of the nineteenth century. Judo became popular as a participant sport after World War II, adopted the characteristics of modern sports, and became a part of Olympic competition in 1964.

Modern Olympic Games

Although well-known transnational sporting contests include the America’s Cup in sailing (1857), Davis Cup in tennis (1900), Ryder Cup in golf (1927), Asian Games (1951), Commonwealth Games (1930), and World Cup in soccer (1930), the most important event for the globalization of sport has been the quadrennial Olympic Games that began in 1896. It was the dream of the Frenchman Baron Pierre de Coubertin (1863–1937) to promote world peace through sports competition and a revival of the ancient Olympic Games. He persuaded seventy-eight delegates from nine nations at a meeting at the Sorbonne in Paris in 1894 to support the idea, and the first meeting took place in Athens. Although the statistics are in question, the first games seem to have involved 311 athletes from 13 nations performing for 70,000 spectators. The Olympic Games have persisted since 1896, although they were not held during World War I or World War II, and they were disrupted by major boycotts in 1980 and 1984.

The Olympics have been a showcase for the world’s best athletes and for rivalries between political ideologies. The Cold War antagonism between the United States and the Soviet Union reflected in the games between 1952 and 1992 resulted in technological improvements in equipment, venues, and training, the erasure of the amateur code that had hitherto excluded professional athletes, and the acceleration of female participation in sports. Title IX of the United States’ Educational Amendments Act of 1972, which ordered equal treatment for female athletes in schools, was instituted in large part so U.S. female athletes could compete more successfully against Soviet bloc female athletes in athletic competitions.

Commercialization of Sports

The commercialization of sports, driven by the fantastic amounts of money produced by advertising on televised events, has created international stars such as boxing wit Mohammad Ali (b. 1942), basketball wizard Michael Jordan (b. 1963), and soccer

phenomenon David Beckham (b. 1975). Their endorsement of products has helped to create an international market for sports equipment, affected labor markets in Asia, and enhanced the growth of companies such as Nike that market the majority of sporting gear and equipment in the global market. Professional sports stars have thus become an international commodity.

One disturbing aspect of international competition has been the increasing use of performance-enhancing drugs, a trend that started with Soviet weightlifters in 1952. Illegal drug use was carried to an extreme by East Germany until the disintegration of the Soviet bloc in 1991, and it has been continued in a systematic way in China. Performance enhancement with anabolic steroids, testosterone, human growth hormone, and possible gene alteration, however, is not limited to China; it has spread worldwide and penetrated to the lower ranks of athletes. The use of such drugs threatens the fundamental concept of fair competition and reaches beyond athletics to raise a question about changes in human physiology that may even affect the definition of a human being. How this problem is addressed will have a profound effect on the future of competitive sports. At the moment the work of the World Anti-Doping Agency (2000) to test and catch illegal drug users has been widely

accepted and the athletes of the 2008 Beijing Olympics were found to be comparatively drug free.

Srivijaya

Srivijaya was a major trading state and Buddhist cultural center based in southeastern Sumatra. It loosely controlled a regional empire in western Indonesia and the Malay Peninsula between the seventh and eleventh centuries CE. The fortunes of Srivijaya were closely related to conditions surrounding the Indian Ocean maritime trade that linked East Asia and Southeast Asia to the Middle East and East Africa.

The ancient Malay peoples who formed Srivijaya in southeastern Sumatra benefited from a strategic position for maritime commerce and intercultural exchange. The Straits of Melaka between Sumatra and Malaya had long served as a crossroads through which peoples, cultures, and trade passed or took root. The prevailing climatic patterns in the South China Sea and Indian Ocean allowed ships sailing southwest and southeast to meet in the Straits and exchange goods. Some Malays specialized in maritime trade to distant shores. By the third century BCE Malay sailors procured cinnamon grown in China, which was carried, possibly by the same Malays, to East Africa or Arabia, from where it was transported to Europe. Between the seventh and eleventh centuries CE, Srivijaya would become a loosely federated empire whose fortunes and connections depended on trade.

Early Indonesian Commerce and Trading States

By early in the common era small coastal trading states based on lively ports had emerged in the Malay Peninsula and Sumatra; these enjoyed an international

reputation as sources of gold, tin, and exotic forest products. Between the fourth and sixth centuries the overland trading routes between China and the West along the Silk Roads through Central Asia were closed off by insecurity and warfare between rival tribal confederations, increasing the importance of the oceanic connection. Just as various Central Asian societies became important because of international commerce, some Southeast Asians benefited from the growth of seagoing trade between China and Western Eurasia.

Beginning around the first century CE, Indian traders and priests began regularly traveling the oceanic trade routes, settling in some of the Southeast Asian states, where they married into or became advisers to influential families. They brought with them Indian concepts of religion, government, and the arts. Hinduism and Mahayana Buddhism became important in the region, especially among the upper classes. By 800 a Buddhist world incorporating many distinct societies stretched from the Indian subcontinent eastward to Japan, and it included the Straits of Melaka. Some Indian-influenced kingdoms in Southeast Asia were based largely on agriculture, such as the inland Khmer kingdom of Angkor. Others depended heavily on maritime trade, including the states alongside the Straits of Melaka. These contrasting patterns represented a skillful adaptation to the prevailing environment.

Mercantile Kingdoms in Sumatra

Throughout the first millennium CE a complex and increasingly integrated maritime trading system was gradually emerging that linked the eastern

Mediterranean, Middle East, East African coast, and India with the societies of East and Southeast Asia. A vigorously mercantile variation of Indian-influenced culture emerged to capitalize on this trend.

In the later seventh century the Sumatran state known as Srivijaya (in Sanskrit the name means “Great Victory”) began to exercise more influence over many of the small trading states in the Straits region, eventually forming a loosely controlled empire over a wide region. Based in the riverine port of Palembang, Srivijaya used its gold, a naturally occurring resource in that part of Sumatra, to cement alliances. Srivijaya’s control was not centralized; rather, the empire was a federation of linked trading ports held together by a naval force that both combated and engaged in piracy. Srivijaya’s kings forged a close political and economic relationship with the powerful Buddhist state ruled by the Sailendra dynasty in central Java, a highly productive rice-growing region.

Srivijaya was also a major center of Buddhist observance and study, attracting thousands of Buddhist monks and students from many countries. In 688 a Chinese Buddhist pilgrim and ordained monk, Yi Jing, stopped off in Sumatra after some two decades of travel in India and Ceylon (present-day Sri Lanka). He was impressed with the vitality of the Srivijayan practice and the devotion of the rulers, and he advised other Chinese Buddhist pilgrims to sojourn for several years in Srivijaya before proceeding to India.

Srivijaya exercised considerable power over the international commerce of the region and maintained extensive trade ties with China. Srivijaya also became a fierce rival of the aggressive Cola trading kingdoms of southern India, with whom it fought repeated battles. By the

eleventh century, destructive conflicts with the Colas and rival kingdoms in East Java reduced Srivijayan power in the region, and the Srivijayan political center moved north to the East Sumatran ports of Jambi and Melayu. Eventually several states in Java, North Sumatra, and Malaya became more influential, and the increasing activity of Chinese trading ships undermined Malay shipping. By the fourteenth century Srivijaya had lost much of its glory.

Eurasian Trade and Islamic Expansion

While Srivijayan power faded, the Indian Ocean routes between Southeast Asia and the Middle East grew even more important between 1000 and 1500, becoming the heart of an extensive trade network. The trading system linked China, Japan, Vietnam, and Cambodia in the east through Malaya and the Indonesian archipelago to India and Sri Lanka, and then connected westward to Persia, Arabia, Egypt, the East African coast as far south as Mozambique, and to the eastern and central Mediterranean. Over these routes the spices of Indonesia and East Africa, the gold and tin of Malaya and Sumatra, the textiles, sugar, and cotton of India, the cinnamon and ivory of Ceylon, the gold of Zimbabwe, the carpets of Persia, and the silks, porcelain, and tea of China traveled to distant markets. Many of these products reached

He comprehends quickly and hears patiently. He understands things at hand and acts accordingly and not according to his sweet will; he does not meddle with others' business unless asked to. This is the prime feature of a wise person. • **From the Sanskrit epic poem *Mahabharatha***

Europe, sparking interest there in reaching the sources of the riches of the East.

Like the Mediterranean, the Indian Ocean developed a spatial unity. No particular state dominated the trading route. The dynamism depended on cosmopolitan port cities like Hormuz on the Persian coast, Kilwa in present-day Tanzania, Cambay in northwest India, Calicut on India's southwest coast, Quanzhou and Guangzhou in southeastern China, and the ports along the Straits of Melaka. These trading ports became vibrant, cosmopolitan centers of international commerce and culture with multinational populations.

Trade networks helped foster the expansion of Islam and the rise of Melaka. Sunni Islam spread widely in the Southeast Asian archipelago from the thirteenth through sixteenth centuries. A common Islamic faith and trade connections linked societies as far apart as Morocco and Indonesia. Islamic culture was a globalizing force, dominating huge sections of Africa and Eurasia. By the fourteenth century Islam was well established in northern Sumatra. Some Hindu-Buddhist rulers of coastal states in the Malay Peninsula and Indonesian islands, anxious to attract the Muslim Arab and Indian traders who dominated interregional maritime commerce and attracted by the cosmopolitan universality of Islam, adopted the new faith.

The spread of Islam coincided with the rise of the great port of Melaka, on the southwest coast of Malaya, which in the early 1400s became, like Srivijaya before it, the region's political and economic power as well as the crossroads of Asian commerce. Melaka also served as the main base for the expansion of Islam in the archipelago, including into the Srivijayan heartland, displacing Buddhism and Hinduism. Like Srivijaya, Melaka also played a crucial role in international trade. Merchants from around Asia

rapidly transformed the port into the region's major trading entrepôt and major link for the Indian Ocean maritime trading network. Gradually, like Srivijaya, Melaka established a decentralized empire over much of coastal Malaya and eastern Sumatra. Today only a few ruins and artifacts hint of the once-great Srivijaya, but its greatest port, Palembang, is a bustling center for Indonesia's oil industry, with a mostly Muslim population.

Joseph Stalin was a revolutionary who became the leader of the Soviet Union in 1927, several years after the death of Vladimir Lenin. Stalin's harsh policies were responsible for millions of deaths, yet his model of government, in various forms, served as method of modernization for more than a billion people living in Communist regimes outside the Soviet Union.

Under Joseph Stalin's leadership during World War II (1939–1945), the Soviet Union managed to defeat Adolf Hitler's German armies and also to intervene successfully in the Far East. Military power gave Stalin a large role in shaping global history after the war. Stalin's brutal dictatorship in the Soviet Union, beginning in 1927, as well as his export of a fatally flawed Soviet system to other states in Eurasia, largely created the Cold War. Despite its terrible costs, the Stalinist model, in modified forms, became an alternative method of modernization for more than a billion people living in Communist regimes outside the Soviet Union.

Early Career

Iosif (Joseph) Vissarionovich Dzhugashvili (1878/79–1953)—known by his revolutionary pseudonym “Stalin,” meaning “man of steel”—became the world's most powerful dictator after World War II. He was born in Gori, Georgia, which was a vassal of the Russian Empire. Stalin, the son of a cobbler, was known in his youth as a tough street fighter, a promising scholar, and a gifted adolescent poet. He followed his mother's wishes and entered the Tbilisi Theological Seminary, but became a Marxist there. He went into

the revolutionary underground in Georgia in 1896, joined the Social Democrats, and then joined that party's Bolshevik faction in 1903. Although an admirer of Vladimir Ilyich Lenin (1870–1924), Stalin did not appreciate all of Lenin's tactical twists and turns. Unlike Lenin, who lived in exile in western Europe for most of the years between 1900 and 1917, Stalin continued to spend much of his early career in the Russian Empire's revolutionary underground. In the revolution of 1905, Stalin was in the thick of things in major cities in Transcaucasia (the area that includes all of Armenia and most of Georgia and Azerbaijan). During the revolutionary doldrums after the suppression of the 1905 revolution, Stalin established himself as a major organizer in Transcaucasia and as a supplier of desperately needed party funds through “expropriations,” although he spent much of 1908–1912 in prison and exile in Siberia.

Rise to Prominence

In 1912 and 1913, during a hiatus between imprisonments, Stalin wrote on the Marxian theory of nationalities (at Lenin's request) and joined the Bolshevik top echelon. (Both Lenin and Stalin believed that nation-states would soon become obsolete, yet they recognized the power of nationalism and promised the ethnic minorities and nationalities in multinational states a certain amount of cultural and political autonomy. This, theoretically at least, included the nations' right to secede.) At the Prague conference of 1912, Lenin made Stalin a member of the Bolshevik Central Committee and an editor of its journal, *Pravda*. Stalin had risen to the top of the party hierarchy along with his close

In this Russian propaganda poster Joseph Stalin claps in response to cheering crowds.

comrade, Grigory Konstantinovich Ordzhonikidze, and Lenin's more theoretically oriented lieutenants, Grigory Yevseyevich Zinovyev and Lev Borisovich Kamenev. In February 1913, Stalin was arrested and sent to Siberia. When he returned from Siberian exile after the February Revolution of 1917, Stalin resumed his position as one of Lenin's right-hand men.

Bolshevik Oligarch

Stalin's laconic manner and plain ways set him apart from the leading Bolsheviks. Lenin, however, appreciated his effectiveness and made him commissar of nationalities in 1917, a member of the Politburo and Orgburo, and, in 1922, the general secretary of the Communist Party—a post that became Stalin's main source of power. Although Lenin criticized Stalin in 1923 and suggested that he be removed from the post, party leaders did not follow through—to their misfortune. Shortly after Lenin's death in 1924, Stalin outmaneuvered all opponents, whether on the left or right wing of the party. He used his power over party personnel to pack party conferences and congresses

and to elect cronies to the Central Committee and the Politburo.

In 1928, against Nikolay Ivanovich Bukharin's advice, Stalin abandoned Lenin's New Economic Policy (which restored a money economy and revived urban retail trade and small industrial enterprises) in favor of crash industrialization and collectivization of the peasantry. Aside from the mass deaths and agricultural catastrophes associated with collectivization, Stalin's policies contributed to a massive famine in 1932 and 1933, especially severe in Ukraine, the North Caucasus, and Kazakhstan. Stalin solidified his position as dictator of the Union of Soviet Socialist Republics (USSR) after the Great Purges of 1937–1938. In the Great Purges, the People's Commissariat of Internal Affairs (abbreviated from the Russian name as NKVD) executed seasoned party members, top leaders and military men, and hundreds of thousands of faceless victims. Was it a brutal but effective method of securing Stalin's power or the actions of a paranoid personality? Most historians see some of each at work. Stalin had educated a new stratum of "Red Experts" with technical degrees,

I believe in one thing only, the power of human will. • **Joseph Stalin (1879–1953)**

Yalta summit in 1945. Left to right: Winston Churchill, Franklin Delano Roosevelt, and Joseph Stalin.

and they quickly moved into the positions of those purged. The new people were Stalin's own and would be his instruments in a command economy (where the government regulates the supplies and their prices) that featured industrial gigantism.

World Affairs

Stalin's diplomatic and military decisions of 1939–1945 contributed to the greatest loss of life suffered by any warring state in the twentieth century, but under his leadership the USSR survived the Nazi onslaught. The USSR formed a winning alliance with Great Britain and the United States, and played the largest role in defeating Germany. Stalin abolished the Comintern, an international association of Communist parties, in 1943, but after World War II he set up a defensive structure of Communist buffer states to the west and an uneasy alliance with Mao Zedong on the east. His behavior in Eastern Europe hastened the Cold War and led Western countries to

form the North Atlantic Treaty Organization. Stalin then formed his own alliance, the Warsaw Pact.

Like Lenin, Stalin believed in the inevitability of imperialist wars, and to prepare for it he created a multinational Communist empire. Stalin opposed the appearance of any independent centers of power in the Communist camp, although he failed in Yugoslavia and China. He ruled over his vast domain in an increasingly irrational manner until his death, but he enjoyed popular admiration to the point of cult worship. Soviet peoples, some of them interned in slave labor camps (the Gulag), suffered tremendously another while their country acquired nuclear weapons and maintained a huge military. Stalin's behavior kept all his colleagues on edge, and they were relieved when he died of a stroke in March 1953. His successors rejected the Stalinist state terror, but the centralized economy resisted change.

Despite its dreadful costs—famines, mass deportations, chronic shortages of consumer goods, blood purges, and totalitarian controls—the Soviet system

created by Stalin appealed to a variety of Third World modernizers, who adapted it to their own purposes. Stalin and those who followed him exported not only an economic model, but techniques of power featuring feared security apparatuses. The Marxist aspects of Stalinism receded in favor of nationalism and de facto imperialism. By the twenty-first century, Stalin became a symbol of Russian power, and his image as mass murderer gave way to that of a strong leader. In Russia and China, Stalin and Mao remain cult figures among ordinary people, and one commonly hears that their policies were “70 percent correct.”

State Societies, The Emergence of

The earliest state societies emerged independently—both Old World (in Mesopotamia, Egypt, and the Indus River valley) and New World (in Mayan regions of Mexico and in the Peruvian Andes)—after several thousands of years of village life sustained by domesticating plants and animals and a storable surplus of agricultural products.

In both the Old World and the New World the earliest state societies developed from village populations engaged in successful, surplus agriculture and the domestication of plants and animals. Although they were different from each other in many ways, they can be generally characterized as highly stratified societies in which lived farmers in the countryside and urban residents, royalty and slaves, merchants, priests, craftspeople, elites, and peasants. Although contacts took place prehistorically among regions, the emergence and evolution of the earliest state societies (a rapid rather than a gradual process) was independent.

Most of the earliest states were not territorially extensive; rather, they were a collection of politically independent cities (or city-states) that shared a cultural tradition and interacted as “peer-polities.” The earliest cities were not small but rather covered several square kilometers in which lived tens of thousands of people. They were centers of innovation in the arts and the recording of information, including the first writing, which appeared in some but not all of the earliest cities and states, and they contained massive ceremonial monuments, such as temples, pyramids, palaces, plazas, and large works of art. These monuments were designed by architects in service to kings

and gods, enriched by the products of craftspeople and traders, and were built by thousands of laborers who owed their existence and livelihoods to the highest stratum of society.

In the Old World the first cities and states appeared in Mesopotamia and Egypt by about 3200 BCE, in the Indus River valley in Asia by about 2600 BCE, and in north China by about 1700 BCE. In the New World the first cities and states emerged in South America along the Peruvian coast and in the central Andes by about the middle of the first millennium CE, in the Maya region of lowland Mesoamerica (Mexico and northern Central America) by about 200 CE, and in the highland region of Mesoamerica, in the cities and states of Monte Alban and Teotihuacán, by about 200 CE. New archaeological and historical research into the emergence of the first states has altered considerably what scholars think about these societies.

The Old World

In Mesopotamia in southwestern Asia the earliest and best-known city-state was Uruk, which at about 3200 BCE reached a size of about 3 square kilometers with a population of about twenty thousand. A few hundred years earlier in Mesopotamia, only modest villages had flourished, none with a population of more than a few hundred. In Uruk the first writing in the world was invented, transforming earlier systems of recording information. The first texts on clay tablets were mainly economic records of deliveries to and disbursements from temples and palaces. However, about 15 percent of the texts consisted of lists of ranks and professions, cities, and names of trees, stones, and even the gods. In short, the first writing

was accompanied by the creation of the first schools and materials for the education of scribes.

The city of Uruk was dominated by a precinct of temples, storehouses, treasuries, and other ceremonial buildings and plazas. New forms of art were created, from large, carved stone vases to small cylinder seals on which a miniature scene was depicted and an inscription placed. These seals were then rolled over wet clay, either on tablets or on pottery vessels, to indicate the ownership of a commodity or responsibility for a transaction. Uruk, like other Mesopotamian cities at the end of the fourth millennium and beginning of the third millennium BCE, was the center of a limited area that included two or three towns, a few hamlets, and farmsteads. The capital cities of the city-states (microstates) contained most of the population in Mesopotamia, the countryside having been substantially depopulated with the growth of the big cities. No political unity existed among the

cities and city-states, although the culture of the cities was distinctively and commonly Mesopotamian. Political unification in Mesopotamia did not occur until almost a thousand years after the emergence of the first microstates, and it did not last long because the Mesopotamian cities reestablished their venerable autonomy.

In contrast to Mesopotamia, Egypt, although lying geographically near Mesopotamia and having contact with it in prehistoric times, was an entirely different kind of state. Instead of a state of politically independent city-states, Egypt at about 3200 BCE was unified, its northern part (Lower Egypt) and southern part (Upper Egypt) brought together into a single state in which it remained for most of the next three thousand years. Egyptian unity made sense because Egypt was mainly a long strip of land along the banks of the Nile River and the land of the Nile River delta. The Nile's predictable and mostly reliable floods provided not only necessary water but also the fertile silts that were the basis for agricultural productivity.

After thousands of years of small villages, urban systems quickly appeared during the late fourth millennium BCE, the first being Hierakonpolis in Upper Egypt, which reached a size of nearly 3 square kilometers, about the size of Uruk and about the same time but not as densely settled, having a population of nearly ten thousand. The first writing in Egypt, hieroglyphic writing, differed in nearly every respect from Mesopotamian writing and appeared at about the same time. The subject of the first Egyptian texts was mainly a celebration of Egyptian kingship and had little to do with the economy of the land. From the start Egyptians displayed a strong sense of political order and stability that was guaranteed by the king and the gods.

Cities in the Indus River valley, in today's Pakistan and north India, emerged extremely rapidly after a long period of farming communities. By about 2600 BCE the most famous cities of Mohenjo Daro and Harappa flourished, both of about 2 square kilometers and more than thirty thousand inhabitants. At least a half-dozen other major cities also existed along the Indus River and its many branches and also along

Ruins in Teotihuacán, Mexico, probably the largest city of the ancient New World. Photo by Arturo Delfin.

another major river, now dried up completely. As in Mesopotamia, the Indus River valley cities were politically independent, although their material culture had characteristic commonalities. The decorations on pottery, the use of standard weights and measures, and the Indus valley script were shared among the cities.

Mohenjo Daro was a carefully constructed metropolis. A ceremonial center included a variety of structures, such as an audience hall and ritual bath. The residential section of the city was separated from the ceremonial center and included both prosperous and less-prosperous houses, well-developed plumbing facilities, and broad boulevards. Indus valley traders journeyed inland to secure precious metals and overseas as far as the Persian Gulf, where their characteristic weights and measures have been found. The Indus valley culture disappeared about 1900 BCE; that is, the big cities grew to such an extent that they could no longer be supported by the farmers in the countryside while village life continued. The Indus valley script, consisting of symbols drawn on seals and pottery,

was much more limited than either Mesopotamian writing or Egyptian writing and has not been successfully deciphered.

From small villages that characterized the north China plain for millennia, large settlements, but with modest populations, emerged at the end of the third millennium BCE. The earliest cities and states in the region appeared during the early second millennium. Erlitou at about 1700 BCE was 3 square kilometers with about forty thousand inhabitants; Zhengzhou at 1500 BCE was equally large; and Anyang at 1100 BCE may have had 100,000 people. These cities were composed of separate ceremonial areas, cemeteries, craft production areas, and residential areas. The cities were the capitals of territories that attempted to control natural resources and trade routes. Unification of these territories did not occur until the third century BCE.

Researchers have found a number of royal graves at the Anyang cemeteries. They are impressive subterranean structures entered by ramps and contain rich bronze vessels and jades and the bodies of retainers

who accompanied royal figures into the afterlife. Researchers also have found “oracle bones.” These were the shoulder bones of cattle and also turtle shells that were inscribed with the first known writing in China. The people of Anyang threw the bones into fires and interpreted the resulting cracks to predict the success or failure of royal persons. After the demise of the earliest cities and of the Shang dynasty (1766–1045 BCE), China experienced a variety of governments and wars that led finally to unification.

The New World

In lowland Mesoamerica the earliest cities and states emerged in the Maya region during the early years of the common era. During the preceding two centuries, however, large cities and vast ceremonial complexes, such as the site of El Mirador, had appeared. El Mirador, however, had no characteristic Maya writing, and thus we do not know about the rulers who must have built the magnificent pyramids and temples there. The first villages in the Maya region appeared only about 1000 BCE, so the transition to states occurred much more rapidly in this region than in any of the Old World examples.

The earliest Maya cities were enormous. Tikal’s central core of monumental structures and plazas, ceremonial causeways and residential areas was not less than 16 square kilometers, and outlying structures extend much farther. The population of Tikal numbered not less than fifty thousand. Other cities were of the size and population of Tikal, but smaller cities existed as well, although the characteristics of Maya cities—the ceremonial structures, pyramids, causeways, inscribed stelae (stone slabs or pillars)—were shared by all of them. Some cities, such as Tikal, achieved control over their rival cities, but large cities such as Caracol were always rivals of Tikal. Maya script, originating during the third century CE—but perhaps having some earlier precursors, according to recent discoveries—recorded dynastic histories, alliances, and wars. During the last centuries of the first millennium CE, most of the Maya cities in the southern lowlands in Guatemala

were substantially abandoned; in the northern lowlands in Mexico Maya cities adapted to new circumstances and survived.

In the Mesoamerican highlands in southern Mexico, the earliest cities and states at Monte Alban (in the modern state of Oaxaca) and Teotihuacán, not far from Mexico City, emerged during the last centuries BCE and the early centuries CE. Monte Alban, the capital of a three-valley region, was situated on an easily defended hill. It had a population of sixteen thousand and then grew to about thirty thousand before its collapse about 750 CE. Teotihuacán was probably the largest city of the ancient new world. At about 200 CE it covered 20 square kilometers and was occupied by an estimated 120,000 people.

The ceremonial complexes at Teotihuacán included six hundred pyramids, the largest of them flanking the “Street of the Dead.” Curiously, because Teotihuacán and the Maya had plenty of contacts, Teotihuacán had no writing system to record its complex transactions and administration. At Monte Alban people used a form of writing, limited and undeciphered, but it seems unconnected to the Maya script. The collapse of Teotihuacán was spectacular. A conflagration (apparently set by an unknown individual or group) destroyed the structures along the Street of the Dead but was not designed to engulf the residential apartment complexes of the city or the craft areas. The site was venerated by the subsequent Aztecs and is occupied today.

In South America, on the northern coast of Peru and in the central Andes Mountains, the first cities and states emerged during the early centuries CE in the former and about 600 CE in the latter. Although the two regions are different—the former requiring utilization of maritime resources in addition to maize cultivation dependent on irrigation, the latter having an agricultural regime of potatoes, quinoa (a pigweed whose seeds are used as food), and maize—they had similar lines of development. The earliest settlements were ceremonial centers; afterward cities emerged. On the coast the earliest states appeared in the Moche Valley, where elaborate burials during the first centuries CE were followed by the first cities.

So, we appeal to Edo hia (all Edo) to heed to our warnings; learn to subordinate the interest of self to that of the whole community; see yourself first as ovbiedo (child of Edo) before a member of this party or that Society. It is only by so doing that the strength in you will come out and be sustained . . . • **Oba Erediauwa (twentieth century)**

In the central Andes two sites, Tiwanaku and Wari, emerged about 600 CE and grew to imposing dimensions—about 6 square kilometers. Wari was the more densely occupied of the two sites, with an estimated population of thirty thousand. The two sites were the centers of regional influence, and Wari, in southern Peru, established an empire that extended to the coast and to the north in the interior. Both sites collapsed during the last centuries of the first millennium CE. Wari presaged the rise of the Inca in many respects, establishing an imperial system, distinctive administrative architecture, a road system, and the earliest *quipus* (knotted ropes), which encoded a sophisticated recording system (although it was not a form of writing).

The earliest states worldwide emerged when populations were attracted to settlements, transforming them into cities and resulting in depopulation of the surrounding countryside. The earliest cities grew as defensive locations offering military protection from neighbors, as the locations of central shrines and pilgrimages, as environmentally favored locations for agricultural production, and/or as key points on trade and communication routes. The territories controlled by cities, and their states, varied considerably. Some states were small—city-states often co-existing with other city-states—whereas others were territorially expansive, such as Egypt, or centered on single cities that controlled their regions, such as Teotihuacán or Wari.

For human civilization there was no turning back from the way of life in the earliest cities and states.

Larger states and empires emerged, trade and warfare increased, and the pace of innovation in social life increased exponentially and often in unpredictable ways.

State, The

States evolved to organize large numbers of people in common endeavors. The first rulers claimed authority from the gods that people worshiped and established armies to defend their territories. As the principal units of civilization, states built cities and roads, established markets and monetary systems, conquered new lands, and waged war, all in the name of self-preservation and protecting their people.

Almost everywhere, people pay taxes and obey laws enforced by separate sovereign states. But during most of the time humans have walked the Earth states did not exist. For thousands of years, small bands of hunters and gatherers as well as the earliest food producers lived without rulers, without officials, without rents and taxes, and without the protection, costs, and services that states brought to later generations.

States arose with cities; their great advantage was that states could organize common effort among large numbers of people. This allowed states to expand their boundaries at the expense of less well-organized neighbors, until, today, only a few isolated, stateless peoples survive in places such as the interior of New Guinea, in the Amazon and Southeast Asian rainforests, and in African deserts.

Early Rule

Not much is known about how states began. Written records that allow historians to find out about the past were invented to keep track of tax payments, and only by degrees was writing used for other purposes. We do know that in the land of Sumer in southern

Mesopotamia (modern Iraq), where the first cities appeared about 3500 BCE, priests were the first rulers. They claimed to serve and communicate with the gods who, they believed, controlled weather, harvests, and all other aspects of the natural and human environment. Persuading common people to secure divine protection for their harvests by giving part of their crop to the gods perhaps seemed a prudent form of insurance against disaster. But in practice it meant handing over grain, wool, and other valued goods to priests, the gods' servants, as a tax. They used some of their tax income to feed workers who built monumental temples to house the gods and busied themselves keeping the gods happy by offering them food, drink, and every other comfort they could think of. Part of the taxes also went for the priests' own support and for the support of those who collected grain from everyone else and kept tax records. Priests also used extra food to support male and female artisans who manufactured fine woolen cloth to clothe the gods' images, and they traded extra cloth far and wide with outsiders, who in return supplied the temples with a great variety of precious goods for use in temple rituals.

By seeking to satisfy the gods so energetically, the priests of Sumer mobilized large-scale common effort across long distances and among different peoples. New skills multiplied, so did new ideas of how to please the gods, and soon the wealth and splendor of Sumerian temples and cities surpassed anything others could match. But conspicuous wealth quickly attracted armed raiders from afar, so priests soon began to need trained warriors, equipped with metal weapons and armor, to repel attacks successfully.

An Uneasy Alliance

After 3000 BCE, constructing massive city walls rivaled temple construction; warriors soon clashed with priests when it came to deciding what needed to be done to keep everything safe and secure. Warfare intensified over time. Sumerian cities started to form rival alliances and fight one another. By the time of Sargon of Akkad (c. 2360–2305 BCE), the first conqueror on an imperial scale, warriors had attained primacy in affairs of state, though to make their power secure, military rulers still needed priests to assure divine help. Accordingly, an uneasy alliance between soldiers and priests became characteristic of subsequent centuries of Mesopotamian statecraft and pervaded most of subsequent world history as well.

Imperial rulers had two persistent problems. One was to defend themselves against rivals to their authority, either unwilling subjects and/or neighboring states and peoples. The other was to choose capable officials to collect taxes, enforce laws, and obey instructions without arousing too much local resistance. Keeping reliable records, rewarding those who served them well, and getting rid of inefficient or disloyal subordinates was a full-time job for rulers and for the small number of high officials with whom the rulers discussed what ought to be done day after day.

Collectively, rulers and the civilian and military subordinates who served them constituted an unstable array of separate rival states; and the unending tumult of domestic struggles and foreign wars that resulted constitute the backbone of traditional history.

For a long time, the mingling of military with priestly power that emerged in Mesopotamia by the time of Sargon of Akkad remained the civilized norm. To be sure, other early civilizations followed different paths toward imperial statehood, often combining military and divine authority in a single person from the start. Menes, the first Egyptian pharaoh, for example, claimed to be a living god as well as leading the army that united Egypt for the first time, and all his successors continued to claim to be gods. Likewise, Chinese emperors ruled by virtue of the Mandate of Heaven (divine justification for their rule) maintained by their personal participation in religious rituals, while they also commanded large armies, sometimes in person but more often through subordinate generals. Similarly, Japanese emperors claimed descent from the sun goddess as recently as 1945, even though through most of Japanese history local warrior chieftains and clan leaders governed Japan without much regard for reigning emperors' wishes. In the Americas also, priestly authority seems to have been initially preeminent and then was subsequently challenged by

A stela commemorating Ur-Nammu, king of Ur in Mesopotamia circa 2000 BCE, shows him receiving the order to build the Ziggurat. Library of Congress.

military leaders in much the same fashion as in the Old World. But information from the Americas is very scant since readable texts are far fewer.

In some places—among Phoenicians on the east coast of the Mediterranean Sea and in ancient Greece and parts of Italy, small city-states arose after about 800 BCE. They first were ruled by kings, but in many Greek cities and later in Rome, magistrates elected for a single year eventually displaced hereditary rulers. Thereafter, elected magistrates divided authority with popular assemblies of citizen-soldiers and councils of wealthier landowners in an unstable and ever-shifting fashion until the Roman Emperor Augustus united the shores of the Mediterranean into a single imperial state in 31 BCE.

Religious Influence

The ancient Greek and Roman city-states remained exceptional inasmuch as they paid little attention to priesthoods and religion and relied on part-time citizen armies. But this departure from civilized norms changed when the Roman army became full time and professional (107 BCE) and priests gained far greater importance after the Emperor Constantine legalized Christianity and his successors made it the official religion of state (379 CE).

Islam reinforced the role of religion in affairs of state when the Prophet Muhammad introduced a new revelation of God's will that claimed to correct and

supersede both its Jewish and Christian predecessors. A long series of victories against the Roman and Persian empires in western Asia and throughout North Africa and Spain (634–732 CE) seemed to prove that the God Muslims, Jews, and Christians worshipped favored the Muslims. Nonetheless, Christianity survived, mainly in Europe. Missionaries spread it northward among Germanic and Slavic peoples—a process more or less completed when Lithuanian rulers accepted Roman Catholicism after 1378. Islam likewise continued to make converts on every front—northward among Turks, eastward into India and Southeast Asia, and in both eastern and western Africa. Until as late as 1669, Muslims also advanced into Europe after the Ottoman sultan Mohammed extinguished the last remnant of the Roman Empire by conquering Constantinople in 1453. Muslim-Christian rivalries still affect international affairs in our own time, and the hold of religion on human minds and feelings remains intense.

Waging War

Until well after the year 1000, states everywhere were usually ruled by kings or emperors who spent most of their effort waging war and preparing to repel attacks. Enormous resources were directed toward building fortified castles and walled cities. The Romans and Chinese even tried to safeguard endangered frontiers by building walls scores and even hundreds of miles

Leon Cogniet, *Battle of Heliopolis* (19th c.). Oil on canvas. The battle marked the beginning of the end of Byzantine rule in Egypt and became part of a pattern of Muslim conquests extending as late as 1669.

in length. Across the centuries, attack and defense alike required more and more elaborate methods and materials, and collecting enough metal and finding skilled artisans to make the best armor and weapons was always a matter of vital concern for rival states everywhere. Making more and more powerful weapons, and fortifying against them, was the most unstable aspect of technology throughout the civilized world; training soldiers to use those weapons efficiently was also important for achieving military success. The effort paid off in the sense that states spread their power over more and more of the inhabited world, even though danger from rival states remained just as great as before.

States built roads to speed marching armies on their way to battle that were also useful for commerce. They built specialized warships using pioneering new techniques in shipbuilding. Occasionally, states also sought to appease the populace of capital cities by organizing grain shipments to assure food supplies

and arranging chariot races and other ceremonies for popular entertainment. But state-managed welfare services for the poor and ill—so important today—were unusual. Religious institutions did something to fill the gap, but private families and charitable neighbors were mainly responsible for whatever help needy persons received.

Money and Trade

From the start, military predominance in matters of state was affected by the persistent problem of how to gather enough raw materials and skilled artisans to make the weapons they needed. Metallic ores in particular often had to be mined and refined in remote locations and then carried to cities where artisans turned them into weapons. Rulers and soldiers could not manage this process in person. Instead they relied on traders and local suppliers, who worked for pay and profit. The invention of coined money about 550 BCE smoothed and accelerated the exchanges of goods and services involved in weapon making and enlarged the scope and reach of peaceable markets as well. In time, states found it convenient to collect taxes in cash instead of in kind, whereupon the money power exercised by bankers and merchants became great enough to affect even the mightiest of states.

Evidence of the power of money in state affairs showed up in the eastern Mediterranean coastlands and eastward to Iraq after Alexander of Macedon's conquests (334–323 BCE) and toward the end of the Roman republic. Thereafter, market relations based on more or less voluntary buying and selling remained a powerful supplement and occasional rival to military and priestly command as a way of coordinating human labor among numerous and far-flung populations. Oddly enough, Christian monasteries and Buddhist monks played a conspicuous part in spreading habits of buying and selling more widely throughout Europe and Asia during the early middle ages when state-organized taxation diminished after the collapse of the Roman Empire and Han dynasty.

A decisive shift came after 960 CE when the Chinese government began to collect taxes in cash from

“The death of the property tax!” Taxes were “born” along with states; although unpopular, they are integral to the states’ success.

ordinary peasants, compelling millions of persons in the course of the next century to find something to sell. They were able to do so since cheap and safe transportation along the rivers and canals of China made even small differences of price an effective stimulus for local, specialized production. Wealth increased, inventions proliferated, and Chinese goods and skills soon began to spread both overland across the steppes and by sea to India and the east coast of Africa. Even the remote Mediterranean became the seat of a general commercial revival when Italian merchants started to compete with Muslim traders.

As a result, enhanced money power presented states and rulers throughout Eurasia with new challenges. In China and the rest of Asia, bankers and merchants remained less powerful than military rulers and officials. But in some parts of Europe, merchants came to govern sovereign city-states, and, within those cities, market relations, sustained by a far-reaching system of water transport, met fewer obstacles than elsewhere. After 1346 the spread of gunpowder weapons—initially invented in China—made warfare more and more costly, and no single imperial state in Europe ever managed to monopolize the market for such weapons within its borders, as China did in Asia.

As a result, European kings and city-states soon found it necessary to pay money to soldiers and arms makers. When money ran short, especially in times

of war, they often borrowed from bankers. Repayment was always difficult, but repudiating state debts meant higher costs next time, and states that cooperated best with bankers came to enjoy clear advantages in war. First Italy, then the Dutch, and, after 1650, the English pioneered the resulting commercialization of war in Europe, while competing European armies and navies sustained rapid and persistent technological changes that eventually gave them global superiority that became obvious by 1800.

Exploration and Conquest

World balances were deeply affected by the discovery, settlement, and exploitation of the Americas. After the first voyages to the New World, Spain, Portugal, France, and England swiftly established trans-Atlantic empires, and when imported diseases caused epidemic deaths among Amerindians, they transported millions of slaves from Africa to work on sugar plantations and perform other laborious and menial jobs. New, racially mixed populations in the Americas began to supply Europeans with silver, furs, fish, sugar, and other valued commodities, while the European imperial states fought naval wars and sent expeditionary forces to the Americas from time to time, shifting boundaries to and fro, especially in the tropical Caribbean.

After about 1750, three factors came into play that changed traditions of statecraft profoundly. One was large-scale application of inanimate forms of power—flowing water, then steam and electricity. This facilitated empire building by the industrialized nations of Europe throughout Africa and Asia so that by 1914 a handful of European states had seized control of most the Earth.

Second were political revolutions, beginning in 1776 in the Americas and then in western Europe, that engaged whole peoples in politics more actively than before. The resulting intensification of political mobilization also expanded around the Earth. As it did so, local peoples challenged and then displaced their European colonial masters so that, by the late twentieth century, the nations of Asia and Africa were again sovereign.

A third transformation was the radical expansion of state intervention in social and economic affairs. First came mass mobilizations inaugurated during the wars of the French Revolution, 1792–1815. Enormously enlarged armies required unprecedented quantities of supplies of every kind, transforming national economies more drastically than ever before.

Power and Protection

State officials expanded their reach by taking responsibility for the welfare of entire nations. Otto von Bismarck, chancellor of Germany, pioneered this breakthrough between 1883 and 1889 by introducing sickness and accident insurance and old age pensions to wean German working men away from Marxist socialism and assure their loyalty to the newly created German Empire. Other leading European countries followed suit by the time World War I ended in 1918. In 1917 Russian Communists came to power and asserted state control over all economic activity. Not long after, the United States responded to the Great Depression of 1929–1937 with social security legislation for old age and emergency relief projects to put the unemployed to work.

Ever since then public opinion in industrialized countries expected, indeed demanded, that governments intervene in more and more crisis situations—hurricanes, earthquakes, riots, wildfires, epidemics, financial crashes, and the like—to minimize losses and aid distressed populations. States that had once been ruthless tax collectors with little or no concern for the wishes and needs of the taxpayers found themselves claiming—and sometimes really trying—to protect everyone from everything that threatened them. Total success remained impossible, but organized state intervention in emergency situations often did reduce human suffering and save lives.

Yet, simultaneously, the creation of weapons of mass destruction—nuclear, chemical, and biological—equipped a few powerful states with the ability to launch attacks upon one another capable of destroying human life on a greater scale than ever before, and our encroachment on other forms of life, sustained by states and the economies that support them, threatens to upset the global ecosystem drastically, with unforeseeable consequences.

State power has not ceased to threaten as well as to protect humankind. The power to protect also gives states the power to destroy. As states use their sovereign power to protect themselves and their citizens, they remain capable of wholesale, perhaps even of global, destruction.

Steppe Confederations

Steppe confederations are large and militarily powerful state-like structures that emerged many times in the steppes of Eurasia (the vast regions that were populated by pastoral nomads) from the first millennium BCE to the eighteenth century CE. Perhaps the most famous was the Mongol Empire created by Chinggis (Genghis) Khan in the thirteenth century.

Steppe confederations appeared from the first millennium BCE to the eighteenth century CE in regions dominated by pastoral nomads, and for this reason they were very different from the states of the agrarian world. To understand them fully, it is important to be clear about these differences, but regardless of those differences, steppe confederations could be so powerful and so influential that it seems foolish not to regard them as states. This article treats steppe confederations as a distinctive type of state and uses the phrase “steppe confederations” interchangeably with the phrase “pastoralist states.”

Nomadic pastoralists may have lived in the steppes of Eurasia from as early as the fourth millennium BCE. As the archaeologist Andrew Sherratt has shown, their distinctive way of life was made possible by technological changes that enabled pastoralists to exploit domesticated livestock more efficiently by using not just their meat and hides but also their “secondary products”—their traction power, wool, milk, and manure. These could be used while the animals were still alive, so the “secondary-products revolution” greatly increased the amount and variety of resources available to livestock herders, making it possible for entire communities to live almost exclusively from their livestock. By making it possible for communities

to exploit the arid steppes, which were too dry to be farmed, pastoralism permitted the settlement of the huge belt of arid grasslands that extends from Manchuria to Mesopotamia and across North Africa and into East Africa. The most powerful steppe confederations have appeared in the steppes between Manchuria and eastern Europe. Here, the animal of prestige was the horse, though sheep, camels, cattle, goats, and yaks were important components of herds in different regions.

Building Steppe Confederations

The appearance of steppe confederations is curious because pastoralists appear to lack the crucial preconditions for state formation. Pastoralism is far less productive than most forms of farming, so it usually supports smaller and more scattered populations. Because most pastoralists are mobile, they also have little reason or opportunity to accumulate large stores of wealth. Finally, pastoralists live most of the time in relatively self-sufficient small groups so that, except in times of war, they need few of the organizational services that states provide. Small populations, limited wealth, and a high level of self-sufficiency make the appearance of pastoralist states something of a puzzle. How was it possible to build powerful states under such conditions?

The first answer is that pastoralists had military advantages that partly compensated for their demographic and economic weakness. Pastoralist lifeways naturally inculcated military skills, for pastoralists had to learn how to hunt—which required mastery of weapons—how to navigate over large distances, and, particularly in the arid lands of Eurasia, southwest

Asia, and northern Africa, how to ride. The physical demands of dealing with large animals and the harshness of steppe and desert climates inured pastoralists to physical hardships, an advantage in warfare, while frequent raiding provided regular military practice. Though associated mainly with males, military skills were also widespread among women in pastoralist societies. Many accounts, including the ancient Greek historian Herodotus's tales of "Amazons," show that pastoralist women could be formidable fighters, and many steppe burials of women contain large stocks of weapons and armor. The military prowess of pastoralist communities is evident as early as the fourth millennium BCE, for steppe tombs (*kurgany*) from that period contain weapons as well as goods produced in neighboring agrarian communities. Doubtless some of these goods were acquired through trade, but there can be little doubt that even the earliest pastoralists, like their descendants, often used the threat of force

to exact tribute. The earliest written accounts of pastoralist lifeways all stress the significance of military skills among pastoralists. In his famous account of the Scythians, written in the fifth century BCE, Herodotus reported that Scythian leaders organized annual meetings at which those who had not killed an enemy in the previous year were shamed. In the first century BCE, the Han historian Sima Qian (1961, 2: 155) wrote of the Xiongnu, who lived in modern Mongolia, "The little boys start out by learning to ride sheep and shoot birds and rats with a bow and arrow, and when they get a little older they shoot foxes and hares, which are used for food. Thus all the young men are able to use a bow and act as armed cavalry in time of war. It is their custom to herd their flocks in times of peace and make their living by hunting, but in periods of crisis they take up arms and go off on plundering and marauding expeditions." Unlike peasants, pastoralists needed little training before going to war.

The role of kinship in pastoralist societies explains why pastoralist communities could rapidly form large military alliances. Nomadic pastoralists normally lived in small groups of related individuals linked to neighboring groups by ties of kinship or fealty. Family or clan leaders would take important decisions about migration routes or handle conflicts with neighboring families and clans. But violent conflict was common, partly because of the extreme volatility of pastoralist lifeways. Entire herds could be lost in spring frosts or because of epidemic diseases, and those affected by such disasters often had little choice but to steal livestock from other pastoralists. Such conflicts could prompt the rapid formation of local military alliances as local leaders sent riders to seek the support of other pastoralist leaders to whom they were linked by kinship, friendship, allegiance, or past obligations. Where the threat was on a large enough scale, the same mechanisms could bring together huge armies, linking pastoralist tribes over large areas. Herodotus (1987, 4: 119) records that in 513 BCE, when the Persian ruler Darius invaded the Black Sea steppes through modern Romania and Moldova, “The Scythians reasoned that they were not able to resist Darius’ army in a straight fight on their own, and so they sent messengers to their neighbors.” Though not all communities joined the alliance against Darius I, a large number did, and Darius eventually had to retreat in the face of sustained and highly effective guerilla attacks.

Alliances also formed to conduct booty raids. As the supporters of the future Chinggis Khan made clear when they elected him their khan in about 1190 CE, they expected to become rich under his leadership: “When you are made *qan*, we, galloping as a vanguard after many enemies, will bring in girls and *qatuns* (i.e., ladies) of good complexion, palace tents, . . . geldings with fine rumps at a trot, and give them to you” (Christian 1998, 391–392).

Forming effective armies in response to external threats or the prospect of booty was one thing; creating a permanent alliance powerful enough to conquer neighboring states and stable enough to be regarded as a state was quite another matter. As the political

theorist Ellman Service has argued, states are distinguished from weaker political systems because they have mechanisms to prevent splitting along tribal lines. “The state,” argues Service, “is a system specifically designed to restrain such tendencies” (Cohen and Service 1978, 4).

In the agrarian world, large and productive populations generated flows of wealth that could be used to weld regional leaders into a single political system, or to buy the services of armies. However, pastoralist communities generated little in the way of surplus wealth. So, to create a stable tribal alliance, pastoralist leaders had to institutionalize the lure of the booty raid. To bind different tribes into a durable political and military system, pastoralist leaders had to secure a steady flow of wealth from neighboring agrarian regions. It was the creation of such stable mechanisms of tribute taking that turned temporary military alliances into the pastoralist equivalents of states. Though normally exacted from “outsiders,” these flows were the functional equivalent of the taxes that sustained agrarian states. The anthropologist Thomas Barfield has analyzed how such stable flows of tribute were established for the first time late in the first millennium BCE, across the northern Chinese borders. In what was really a systematic form of extortion, the Xiongnu, based in modern Mongolia, threatened to launch devastating raids into China’s agrarian regions unless they were bought off with annual tributes in foodstuffs, silks, and other valued goods. “Just make sure,” a Xiongnu official once explained to Chinese envoys, “that the silks and grain-stuffs you bring the Hsiung-nu [Xiongnu] are the right measure and quality, that’s all . . . If the goods you deliver are up to measure and good quality, all right. But if there is any deficiency or the quality is no good, then when the autumn harvest comes we will take our horses and trample all over your crops” (Christian 1998, 192). As long as Chinese states continued to pay tribute, Xiongnu leaders could lavish gifts on their followers and maintain their loyalty. The key to success lay in the plausibility of the threat, and only a pastoralist leader who had achieved unquestioned authority over large contingents of steppe soldiers

could make such threats with credibility. So in the steppes, state-building normally began with a skillful and charismatic leader creating an exceptionally disciplined following.

Establishing stable flows of tribute from large agrarian states was extremely difficult, which is why pastoralist states appeared much later than the first agrarian states and were also less common, more fragile, and more ephemeral: few lasted more than a generation or two, as they depended so much on the charisma and skill of their founders. However, once a state had been created, there was much that farsighted leaders could do to stabilize them. The most natural step was to launch new wars of conquest that could supply more booty and remind existing tribute payers of the dangers of nonpayment. Eventually, however, all successful pastoralist leaders found they had to build durable bureaucratic and political structures, similar to those of the agrarian world. Even before they became supreme leaders, the most farsighted steppe leaders often built up elite military units or bodyguards that were organized bureaucratically, bound closely to the overall leader, and kept apart from the traditional structures of kinship. The starkest example of such a strategy can be found in Sima Qian's description of how Maodun, the founder of the Xiongnu confederation, built up a highly disciplined personal following. Maodun ordered his followers to shoot at any object towards which he aimed his arrows, and executed those who refused to obey. He aimed, first, at one of his favorite horses, killing all those too fearful to follow his example; then aimed an arrow at his favorite wife, once again executing those who failed to shoot; then he aimed at his father's horse. Finally, he aimed an arrow at his own father. After replacing his murdered father, Maodun deliberately broke up kinship structures amongst his followers, organizing them in units of ten that owed allegiance to each other rather than to kinship units.

At the very top of any successful steppe confederation, the key to stability lay within the ruling family. It was vital to secure the succession and it was vital that the successor be an able leader. This was perhaps the most difficult task to achieve; we can be sure that

all steppe leaders thought hard about it, and some, including Chinggis Khan and Maodun, succeeded in handing power over to sons who were competent enough to hold their empires together. Below the ruling family, structures were created to bind regional leaders to the state. All the most powerful steppe leaders, beginning with Maodun, organized regular meetings of regional leaders. These pastoralist "parliaments" offered the chance to keep an eye on potential rivals, to take rudimentary censuses, to consult about policy, to share worship, and even to hold competitions in a pastoralist equivalent of the Olympic games (of which the modern Mongolian Naadam festival is a survivor). Successful steppe leaders also built palaces or capital cities, with the help of artisans from the agrarian world, in order to demonstrate their wealth and display their prestige. The Mongols, the most successful of all pastoralist leaders, used advisers from conquered regions to help them construct elaborate fiscal systems, rapid communications systems using post-horses, and written laws. As they became more reliant on the resources and the commercial and bureaucratic skills of the agrarian world, some steppe leaders, such as the Seljuks, the Ottomans, and the Mongol rulers of China, eventually moved their capitals into the agrarian world, turning pastoralist states into conventional agrarian states that retained little but a symbolic memory of their pastoralist origins.

Major Steppe Confederations

Powerful alliances of pastoralist leaders may have appeared as soon as pastoralism itself emerged, from the fourth millennium BCE. Certainly, the archaeological evidence suggests that even this early, there were militaristic migrations of pastoralist peoples over large areas. By the first millennium BCE, written evidence appears of large-scale pastoralist attacks, such as the Cimmerian and Scythian invasions of northern Mesopotamia and Anatolia through modern Azerbaijan. By this time, some steppe leaders were being buried in very large, elaborate tombs with slaves, horses, and huge hoards of wealth, which indicates their wealth and power. And it is clear that Scythian leaders north

of the Black Sea exacted tribute from farming communities in modern Ukraine and the Crimea. But none of this evidence suggests the existence of steppe confederations or true pastoralist states, that is, of stable systems of rule capable of sustained tribute taking from neighboring agrarian states.

The first steppe confederation that really fits this definition was the Xiongnu confederation created by Maodun in Mongolia early in the second century BCE. Knowing his father favored a younger brother, Maodun built up the disciplined following of soldiers described earlier, and used it to overthrow his father and remove his father's closest allies. Having established his unquestioned supremacy among the Xiongnu, he then turned on two large neighboring confederations, looting them and enriching his followers. Finally, just as the Han dynasty was establishing itself in northern China, he led devastating booty raids into the region, eventually defeating the first Han emperor, Gaozu (reigned 206–195 BCE). In 198 BCE Gaozu negotiated the first of a series of treaties under which he recognized Maodun as an equal, promised him a royal bride, and agreed to send him annual “gifts” of silk, wine, grain, and other goods. Meanwhile, the Xiongnu had also established tributary relationships with other tribes of pastoralists, and with the many small towns and communities of modern Xinjiang and the Tarim Basin, as well as with some of the cities of Central Africa. Their authority soon reached from Manchuria to Central Africa, making the Xiongnu state one of the largest of all pre-modern states. The relationship with the Han was the key to Xiongnu power simply because of the huge wealth and prestige that the relationship brought them. It was maintained for almost sixty years until a more powerful Han ruler, Wudi (reigned 141–87 BCE) decided that the price demanded by the Xiongnu was too high, and launched a decades-long war on the Xiongnu. Though weakened and never again the diplomatic equals of the Han, regional Xiongnu leaders retained significant power for the best part of three centuries.

The history of the Xiongnu was to be repeated several times during the next two thousand years. In 552, a dynasty known as the Ashina created the

first Turkic Empire. Like the Xiongnu state, the first Turkic Empire was created from a base in Mongolia. It also owed much to the charisma and skills of its founders, the brothers Bumin and Ishtemi. Within fifteen years of its creation, it reached from Manchuria to the Volga river, negotiating on equal terms with all Eurasia's superpowers: China, Persia, and Byzantium. However, the empire fell apart within two generations of its founding, partly because of conflicts within the ruling family. A second Turkic Empire was established in 683 and lasted until 734, though it never reached as far west as its predecessor. It was overthrown by a Uygur dynasty that lasted for almost a century, until 840.

A Mongol ruler, Temujin (c. 1160–1227), created the greatest of all the steppe empires in the early thirteenth century. Like Maodun, Temujin made his way in a hostile environment of vicious tribal and personal conflict. He built up a loyal and disciplined following, and in 1206, at a gathering of regional leaders he was elected overall khan, or *Chinggis Qan* (from which derives the popular Anglicized version of the name, Genghis Khan). Chinggis Khan led Mongol armies in wars of conquest in northern China and Central Asia. After his death, his successors conquered the rest of China, Russia, and Persia. In the 1260s his grandson Khubilai Khan briefly claimed sovereignty over Mongolia, China, Central Asia, Russia, and Persia—the largest land empire ever created.

Other pastoralist states were created in Mongolia in the sixteenth and seventeenth centuries. The Jungar Empire, created in western Mongolia in the late seventeenth century and crushed by China's Qing dynasty in 1758, probably counts as the last great steppe confederation.

The largest and most influential of steppe confederations emerged in the steppes north and west of China, probably because from there they could extort wealth from the largest and wealthiest power on earth. But other steppe confederations appeared further west. At the western end of the steppes, the most powerful pastoralist confederations appeared in Hungary, from where they could extort the wealth of the Roman and Byzantine empires. The best known

of these states are those of the Huns (in the fifth century) and Avars (sixth century), though earlier pastoralists too had briefly extorted wealth from their agrarian neighbors in eastern Europe. Both the Hun and Avar states extracted large amounts of wealth from their neighbors, but neither survived as a major power for more than a generation, perhaps because the steppes of Hungary offered too small a base for really large pastoralist armies. In central Asia there appeared many powerful pastoralist alliances, some of which endured for several generations. The geography of Central Africa denied them the possibility of extorting wealth on the scale of the Mongols or even the Huns; their wealth came from the many small oasis city-states of the region. The most powerful of the Central African steppe confederations, the Kushan Empire (c. 45–c. 230), based its power primarily on agrarian communities, and, despite its pastoralist origins, should really be counted as a pastoralist dynasty ruling agrarian states. The same could be said of the Seljuks, who conquered much of Central Africa in 1040 and went on to conquer much of Persia, Mesopotamia, and Anatolia within a generation.

North and west of the Caspian Sea, the peasant migrations that were to lay the foundations for the emerging states of Russia created new opportunities for pastoralist leaders to exact tribute. The Khazar Empire was established along the western shores of the Caspian sea in the early seventh century by rulers from the Turkic Ashina dynasty. It lasted for more than three hundred years and was eventually destroyed in 965 by an army from Kievan Rus' (a principality with its capital at Kiev). Its heartland remained in the lands just north and west of the Caspian, and its rulers always retained a sense of their pastoral origins. It exacted tribute from neighboring pastoralists and from agricultural communities in the lands of modern Russia and Ukraine; it also became a major international power, negotiating on equal terms with both Baghdad and Constantinople. Its wealth came from a wide variety of sources, from local tributes, from taxes levied on trade, and from taxes levied on agrarian populations in the Caucasus and Rus'. After the Mongol conquest of Rus' in

1237–1241, the heirs of Chinggis Khan's eldest son, Jochi, established a state often known as the Golden Horde or the Kipchak khanate. For more than a century this state successfully exacted tribute from the Caucasus and from Rus' before fragmenting into smaller regional states, none of which managed to establish such stable flows of tribute.

Steppe Confederations in World History

Though it makes sense to regard them as states, steppe confederations were very different from the agrarian states that give us our conventional images of statehood. Built with limited resources, steppe confederations had to rely mainly on external sources of revenue, taken by force from agrarian communities very different from their own. The military skills inculcated by pastoralist lifeways made pastoralists formidable in warfare, but establishing stable systems of tribute was possible only under the most powerful and skillful of steppe leaders. Maintaining durable flows of tribute was much more difficult than mounting periodic booty raids, which explains why so few pastoralist leaders succeeded in creating true pastoralist states, and why pastoralist states rarely survived for more than two or three generations. But when pastoralist states did emerge, they could prove extremely powerful and extremely influential. They were some of the largest states that have ever existed, and their impact on Eurasian history was at times revolutionary.

Sugar

Sugar, a dietary source of sweetness and energy, can also act as a binder, stabilizer, caramelizer, and bulking agent. Throughout much of history sugar was a luxury. The expansion of the industry in the Western Hemisphere increased the supply of sugar in Europe, making it less costly; it also linked sugar production with slavery and plantation agriculture, thus affecting lasting political, economic, social, and cultural consequences.

The familiar white crystals in the sugar bowl on the breakfast table are virtually pure sucrose, an organic chemical defined technically as a disaccharide carbohydrate. Other common disaccharides are lactose, the sugar found in milk, and maltose or malt sugar. Sucrose is a product of photosynthesis, the complex biochemical process whereby green plants use light energy to combine aerial carbon dioxide and hydrogen from soil water into rings of carbon atoms to which atoms of hydrogen and oxygen are attached, usually in the same ratio as in water (hence “carbohydrate”). It is found in the sap of many plants, where it functions as stored energy, but the commercial article—and the substance usually meant when people speak of sugar—is chiefly extracted from sugarcane or sugar beet.

Sucrose is composed of two simple carbohydrates, likewise very prevalent in nature: glucose (also called dextrose and grape sugar), which occurs in fruits, plant juices, and honey, as well as in blood, and fructose (levulose or fruit sugar), which occurs in the free state, notably in honey. Sucrose is easily inverted by acid hydrolysis or enzyme action into glucose and fructose, both monosaccharides (so named because

they cannot be reduced to smaller carbohydrate molecules) that share the same chemical formula but differ in atomic structure and are interconvertible by chemical and biological reactions. Fruits, young vegetables, floral nectar, and the sap of certain plants and trees owe their sweet taste to the presence of different sugars. As a saccharide, sucrose is also related to starch, another form of stored energy consisting of long branching chains of glucose molecules.

Multiple Sources

These affinities explain how sugar can be obtained from two quite dissimilar botanical sources: sugarcane, a perennial giant grass grown in the tropics and subtropics for its stalks and exploited industrially for more than two millennia, and sugar beet, a temperate-zone biennial of the goosefoot family, which has been harvested for the sugar in its roots for barely more than two centuries. They also explain how sugar has more recently been partially replaced in manufactured foods and beverages by starch-based sweeteners. And they explain minor sweetener sources, some going back to ancient times, such as boiled-down grape juice; fig and date syrup; the sap of palms, the maple tree, and sweet sorghum; and the exudations from certain trees and shrubs. Like sugar, honey—the first concentrated sweetener known to humans—is ultimately a product of photosynthesis. Bees making honey and humans processing cane or beet to crystal sugar are basically doing the same thing—both extract dilute sugar solutions from plants and convert them into forms easier to handle and storable by evaporating unwanted water.

This vintage chart showing sources of sugar and methods of production does not indicate sugarcane plantations of the Caribbean, recognized as profitable even in the early sixteenth century.

All forms of sugarcane are species or hybrids of the genus *Saccharum*, a member of the large family of Gramineae. Their botanical derivation from ancestors in northern India or China is still debated, but cane probably became a cultivated food plant, originally selected for chewing, in eastern Indonesia, New Guinea, or the Philippines from about 4,000 to 3,000 BCE. It eventually spread eastward across the Pacific and northwestward to India—where crystalline sugar has been made since at least the fifth century BCE—and thence by way of Persia and the Mediterranean basin to the Atlantic seaboard, finally reaching the New World in 1493, with the second voyage of Columbus. The expansion of the industry in the Western Hemisphere had two effects. First, it increased the supply of sugar in Europe, making it less of a costly rarity. Even so, British per capita sugar consumption in the early 1700s is estimated to have averaged just four pounds a year, or about a teaspoonful a day. Second, it linked sugar production with slavery and plantation agriculture on a scale far greater than anything previously seen in the Old World, with lasting political, economic, social, and cultural consequences.

Sugar beet, on the other hand, a type of *Beta vulgaris* L. (red garden beet, Swiss chard, and fodder beets are of the same species), is a child of science. The plant is known to have been used as a vegetable and medicinally in Greek and Roman times. But it was not until 1747 that a German professor, Andreas Sigismund Marggraf (1709–1782), reported having extracted from red and white beets a substance identical with cane sugar. Toward the end of the 1700s, another scientist, Franz Carl Achard (1753–1821), began to grow white beets for sugar, opening the world's first beet sugar factory in Silesia in 1802. Expanding under the umbrella of state protection, beet sugar production became an important driver of the agricultural and industrial development of nineteenth-century Europe.

Whether starting from cane and beet, a sugar factory in essence performs a series of solid–liquid separations: (1) extraction of the juice, with fiber or pulp the residue; (2) purification of the juice, removing

The sugarcane plant, a perennial giant grass, grows in the tropics and subtropics.

nonsucrose substances; (3) concentration of the purified juice to syrup; (4) crystallization of the sucrose in the syrup by further evaporation; (5) separation of the crystals from the syrup. While some high-quality raw cane sugar is sold for consumption, most undergoes additional refining—on-site or in a separate plant—by washing and redissolving the crystals and further clarifying and decolorizing the resulting solution. The clear syrup is then again boiled until crystals form or is made into liquid sugar. White sugar can also be produced directly after a more thorough purification of the juice, as is now done in some cane sugar factories and throughout the beet sugar industry.

A Staple Commodity

No fewer than 115 countries produced sugar in 2004, but just five areas—Brazil, India, the European Union, China, and the United States—accounted for around 55 percent of global output. World consumption of

Everything is a miracle. It is a miracle that one does not dissolve in one's bath like a lump of sugar. • **Pablo Picasso (1881–1973)**

sugar from industrial-scale processors amounted to some 130 million metric tons, white quality, equivalent to about 21 kilograms per person. Roughly three-quarters came from sugarcane and the rest from sugar beet. In addition, on the order of 12 million metric tons of indigenous types of cane and palm sugar were produced by small rural enterprises, mainly in Asia and Latin America. Average annual per capita sugar consumption by country ranged from less than 10 kilograms to more than 60 kilograms, depending on economic factors as well as national habits and tastes. At higher living standards sugar is mainly consumed as an ingredient of processed foods and drinks, where it now competes against high-fructose syrups, made chiefly from corn, particularly in the United States. In early 2010 (according to reports in *Bloomberg*, *Businessweek*, and *Financial Express*), the production of sugar was slated to fall short of demand by 14 million tons for the year (about enough to make 346 billion cans of Coca-Cola), and the price of refined sugar on the futures market soared to reach a twenty-year high at 30 cents a pound. Supply interruptions due to too much rain in Brazil (the world's largest producer) and not enough rain in India (the world's second-largest producer and first largest consumer in 2010) were the culprit.

Like starchy foods, sugar is a source of dietary energy, providing nearly 4 kilocalories (about 16 kilojoules) per gram. As such it is often denounced as “empty calories.” In one sense the charge is true—even raw sugar supplies practically no minerals, vitamins, fiber, or protein and excessive consumption contributes to obesity. In a more important sense, however, the charge misses the point. Whereas potatoes or rice can be eaten alone by the plateful, it is hard to swallow even a teaspoonful of sugar without dissolving it in a liquid. Sugar is first of all a sweetener, although in that role it can be replaced by high-intensity sweeteners. But it also fulfills other functions, acting as a binder,

stabilizer, and bulking agent. It caramelizes on heating to form complex coloring and flavoring substances, and part of it is inverted during food preparation, the resultant monosaccharides reacting with other recipe components to lend aroma and browning to the final article. This increases the color, luster, and flavor of bread crust, for example. Well known, too, is sugar's antimicrobial effect in fruit preserves, jellies, and jams, where a high concentration of dissolved sugar inhibits the growth of spoilage microorganisms.

Ultimately, what has made sugar a staple food is that it enhances the beverages and foods in which it is ingested.

Sui Wendi

(541–604 CE)

FOUNDER OF CHINA'S SUI DYNASTY (581–618)

Wendi (family name Yang Jian) founded the Sui dynasty in 581 CE. His greatest achievement as emperor was the reunification of north and south China. An able administrator, he built a new capital city, reduced taxes, and created granaries to guard against famine. A devout Buddhist, he expanded the number of monasteries and monks throughout the country.

Emperor Sui Wendi oversaw the reunification of China for the first time since the fall of the Han dynasty in 220 CE. During the brief Sui era (581–618 CE) and the Tang dynasty (618–907 CE) that followed, China emerged as the cultural and political model for much of East Asia. A cautious but effective administrator, Sui Wendi initiated a number of governing reforms that were the precursors of both the civil-service examinations and state bureaucracy that were utilized by subsequent dynasties until the early twentieth century. Under the reign of Sui Wendi, Buddhism, a religion imported from South Asia, flourished in China and came to play an important role in the shaping of Chinese culture alongside the native philosophies of Confucianism and Daoism. In an effort to cement the union of northern and southern China and to improve internal transportation and communications within the empire, Sui Wendi initiated the building of a series of canals and waterways commonly referred to as the Grand Canal, a project that linked his kingdom's two major rivers, the Huang (Yellow) and the Yangzi (Chang). The stability and prosperity that were ushered in during Sui Wendi's reign were disrupted when his son, Sui Yangdi (569–617), succeeded the throne in 605, but the cultural, economic, and institutional foundations upon which

the Tang dynasty would later build were laid by the first emperor of the Sui.

Sui Wendi was the reign title of Yang Jian, who was born into an aristocratic family from the region west of the ancient capital of Chang'an in northwest China. Yang Jian's family had for six generations not only served as officials to the region's Turko-Mongol rulers, but also intermarried with the local non-Chinese elites. As a youth, Yang Jian received his education first at a Buddhist temple and later at an imperial academy in the Western Wei capital, where he was taught the basic tenets of Confucian philosophy. Through the influence of his father, Yang Jian received his first minor official post at the age of thirteen. He was quickly promoted over the next few years, and when his father died in 568, Yang Jian inherited his title, becoming the Duke of Sui and an important figure in the Northern Zhou court.

In addition to performing well in his administrative positions, Yang Jian was also a gifted military commander who proved himself during the wars between the competing Chinese states of the sixth century. In return for his loyalty and service in the campaign against the Northern Qi kingdom, he was given the title of "Pillar of the State" by Emperor Wu, the Northern Zhou emperor, and appointed military commander and administrative governor first over the Great Plain in northern China, and then over the newly conquered southern regions. When Emperor Wu died in 578, he was succeeded by the Crown Prince Yuwen Bin, who was also Yang Jian's son-in-law. The new ruler quickly proved to be an unstable tyrant who dismissed many of the kingdom's most able officials. Fortunately, Yang Jian, as the emperor's father-in-law, was spared during these purges, but

A gem is not polished without rubbing, nor a man perfected without trials. • Chinese Proverb

Emperor Sui Wendi, a detail from the painting *Portraits of the Emperors*, by the seventh-century artist Yen li-pen.

when Yuwen Bin abdicated after only eight months in power and transferred the throne to his six-year-old son, Yang Jian's position became less tenable. The situation at the court deteriorated in the spring of 580, when the retired emperor threatened his wife and father-in-law with death. At that point, Yang Jian organized a coup against the ruling house.

In the late summer of 580, the Zhou forces were defeated. This military victory was followed by a massive purge of the royal family, during which almost sixty persons were murdered at the court, including the young emperor, Yang Jian's grandson. The Sui dynasty was founded in 581 in northern China, although all of the southern regions were not pacified until 589.

Once in power, Yang Jian, now the emperor Sui Wendi, began to consolidate his power and to

persuade his subjects that he had not usurped the throne. Claiming that he was restoring the glory and stability of the Han dynasty, Sui Wendi had court scholars write works praising his leadership, as well as edicts that improved his genealogy by conferring honors and titles on his father, grandfather, and even great-grandfather. Sui Wendi also secured the support of religious leaders by granting land and making donations to both Daoist and Buddhist temples and monasteries. Nor was Confucianism ignored during Sui Wendi's reign; the emperor fostered the development of imperial Confucianism by supporting a state-sponsored school in the capital.

One of the most pressing challenges that Sui Wendi faced was recruiting officials to govern his growing empire. During his reign, Sui Wendi introduced a system of official selection that involved a personal interview and examination by high officials for a limited number of candidates who demonstrated promise but who were not from aristocratic families. Not only did Sui Wendi believe that talent and merit should be rewarded, but he was also aware of the dangers of corruption within his bureaucracy. To limit this problem, he introduced the rule of avoidance, which dictated that an official could not serve in his place of origin, as there was a danger that an official could favor his family or friends if posted to his home town. To prevent officials from forming new friendships and bonds of obligation, all officials were rotated to new postings every three years. These administrative reforms formed the basis of the Chinese bureaucracy for the next fourteen hundred years.

With support from many sectors of the population Sui Wendi was able to solidify his position and to subdue the last independent Chinese kingdoms, Liang (587) and Chen (589). In addition to waging military campaigns, supporting the development of Buddhism, and reforming the bureaucracy, Sui Wendi also undertook a massive construction project aimed at solidifying his union of northern and southern China. In order to transport the economic and agricultural wealth of the south northward to his capital, and to facilitate the movement of troops and communications, Sui Wendi initiated the construction of a series of canals to link his capital to the Huang River

and to link this northern river to the Chang in the center of his kingdom. Begun in 584 and completed during the reign of his son in 605, the Grand Canal was a massive engineering project that symbolized China's new confidence and prosperity.

Sui Yangdi

(569–617 CE)

SECOND EMPEROR OF CHINA'S SUI DYNASTY

The reign of Sui Yangdi was marked by the building of canals, the construction of grand palaces, and extravagant entertaining. The expense associated with these achievements, along with huge loss of life and burdensome taxation due to wars against the Korean state of Koguryo, resulted in widespread rebellion, Yangdi's ultimate death, and the downfall of the Sui dynasty.

Sui Yangdi was the reign name of Yang Guang, the second son of Yang Jian (Sui Wendi), the Sui dynasty's founder. Sui Yangdi has generally been portrayed by Confucian historians as an immoral ruler and despot. Ruling from 605 to 618, Sui Yangdi not only continued the construction of the Grand Canal, a project begun by his father, but also initiated several other major projects of his own, including work on the Great Wall, and the rebuilding of the cities of Luoyang on the Huang (Yellow) River to serve as an eastern capital and Yangzhou on the Yangzi (Chang) River to serve as a southern capital. Sui Yangdi also moved to extend Chinese control over neighboring territories by sending armies to the west against the nomadic peoples of Central Asia, to the south against the Vietnamese, and to the east in an attempt to conquer the Korean kingdom of Koguryo. These wars, coupled with the taxes and forced labor that were required for the massive public-works projects, resulted in widespread hardship and resentment, and eventually led to the collapse of the dynasty.

Yang Guang's career began early, when at the age of thirteen he received from his father the titles Prince of Jin and Governor of Bingzhou, a strategically important post on the northern frontier. The

emperor also arranged for his son to be married to a princess from the former Liang kingdom in southern China. At the age of twenty, Yang Guang was charged with leading an expedition against the state of Chen, the last independent state in southern China. The campaign was a success and marked the culmination of the Sui reunification of China. Yang Guang was rewarded for his role in the pacification of the south with his appointment to the position of viceroy stationed at the capital of Yangzhou. Aside from periodic trips to report to his father and mother at the imperial capital of Chang'an, Yang Guang remained in Yangzhou for much of the next decade, where he supervised the integration of the southern population and economy into the newly unified empire.

Although his family's roots lay in the northwest region of China, Yang Guang, perhaps due to the influence of his wife, became increasingly fond of the culture of southern China. While serving as viceroy in Yangzhou, Yang Guang worked to cultivate the loyalty of the empire's new southern population. Using his increasing fluency in the regional Wu dialect as well as the personal relationships made possible by his marriage, Yang Guang emerged as a champion of his subjects and secured their support for the new dynasty. In an effort to diffuse anti-Sui sentiments among the former Chen aristocracy, Yang Guang appealed to their religious convictions and issued orders for court-appointed scholars to recopy Buddhist scriptures and texts that had been destroyed during the civil war. He also supported the repair and construction of Buddhist temples and monasteries throughout the area under his command, in addition

Each generation will reap what the former generation has sown. • Chinese Proverb

Emperor Sui Yangdi, a detail from the painting *Portraits of the Emperors*, by the seventh-century artist Yen li-pen.

to hosting banquets for local monks and abbots. Yang Guang not only patronized the dominant religion of southern China, he also supported the building of two Daoist monasteries in the southern capital and the appointment of Confucian scholars who had formerly served the Chen kingdom to positions within his administration.

During a visit to his mother at the imperial capital in 600, Yang Guang became convinced that his elder brother, the crown prince, was unsuitable to succeed to the throne. Yang Guang began to gather allies from among the military commanders and aristocracy and

to plot against his brother. Later that year he presented his father with enough real and manufactured evidence that the emperor issued an edict deposing the crown prince. Yang Guang was shortly afterwards proclaimed crown prince and left southern China to assume his new position at Chang'an. Following his mother's death in 602, Yang Guang was charged with much of the day-to-day administration of the empire. When his father died in the summer of 604, Yang Guang assumed the throne under the reign name Sui Yangdi.

In an effort to placate the powerful gentry and aristocratic families of northern and central China, and to have his administration closer to the eastern and southern reaches of the empire, Sui Yangdi moved the capital 300 kilometers east to the city of Luoyang. Between 612 and 614, in an attempt to restore the former borders of the Han period, Sui Yangdi also initiated three failed attempts to conquer the Koguryo kingdom in northern Korea. These expeditions were unsuccessful, as were similar attempts to pacify the Turks in the northwest in 615 and 617. Despite these military failures, Sui Yangdi did establish military colonies along his borders and some political control over the lesser tribes of the northern steppes.

The military defeats, coupled with the hardship brought about by the construction of the Grand Canal, the capital city of Luoyang, and the repairs to the Great Wall, led to rebellion throughout the empire. By 617 rival claims to the throne were appearing throughout China as civil war broke out. In 618 Sui Yangdi was assassinated and the dynasty that his father had founded collapsed. China remained divided into many petty states and kingdoms until the new rulers of the Tang dynasty reunified China five years later.

Süleyman

(1494–1566)
OTTOMAN SULTAN

In Europe, which trembled at the appearance of his armies more than once, the Ottoman sultan Süleyman I was known as “the Magnificent.” Throughout the Islamic world, he was better known as Kanuni, “the Lawgiver,” and was believed to embody the highest principles of justice and harmony in a ruler. For his force of will and his many accomplishments, Süleyman deserves consideration as one of the great leaders of history.

As sultan of the Ottoman Empire, Süleyman I pursued a policy of militant Islam and imperialism. Süleyman’s deep faith in God and upbringing in the warrior traditions of the Ottoman Turks required that he should someday lead armies in battle, defeat infidels in the *dar al-harb* (“abode of war”), and give law and provide order for the faithful in the *dar al-Islam* (“abode of Islam”). Süleyman’s father, Selim the Grim (1470–1520), had extended the Ottoman Empire past the frontiers of Kurdish and Turkmen potentates into what is now northern Iraq and had conquered Egypt, Syria, and the Arabian Peninsula, bringing the holy cities of Mecca and Medina under Ottoman control.

The Ottoman Empire was not a hereditary monarchy, nor was it elective. Nevertheless, by killing his brothers and their descendants, Selim had cleared the way for the ascension of Süleyman by the time Selim died of cancer in 1520.

The young sultan appears to have been confident, proud, and forceful. According to the ambassador from Venice, Süleyman rewarded his supporters by showering them with gifts and punished those who had not shown loyalty during his ascension. He

gave clemency to those who allegedly had committed crimes against his father, and most important, he rewarded his bodyguard—the janissaries—with liberal cash disbursements. The janissaries were slave soldiers who were supplied by a levy upon the children of Christians. These soldiers trained with the composite bow and firearms and provided Süleyman with a powerful army. The young sultan had cultural interests as well: he wrote highly esteemed poetry, and he commissioned the architect Sinan to beautify the Ottoman capital of Istanbul.

War in the name of religion was at the heart of Süleyman’s view of the world and his understanding of what it meant to be leader of the Ottoman state and its people. Holy war would not only content the janissaries, but also win the favor of God. Süleyman’s subjects shared in the belief that God would approve of such warfare and reward the devout with prosperity. Early in his reign, Süleyman demonstrated his abilities as leader of the faithful in the constant small-scale raids and reprisals that raged back and forth on the border between the Ottoman Empire and the Christian kingdom of Hungary. On 16 February 1521, Süleyman marched out of Constantinople at the head of an army that numbered more than 100,000 men. Forty Turkish vessels sailed up the Danube River in support, and ten thousand wagons brought powder and shot. Süleyman’s army eventually captured the Serbian capital of Belgrade. When the defenders of this town surrendered, they were massacred. It is not known whether Süleyman approved of this atrocity or not. On 18 August 1521, the cathedral of Belgrade was consecrated as a mosque. Even as the great victory was celebrated at home, Süleyman planned yet further conquests.

What men call empire is world-wide strife and ceaseless war. In all the world the only joy lies in a hermit's rest. • **Süleyman (1494–1566)**

Nakkaş Osman, *Süleyman the Magnificent as a Young Man* (1579). Miniature portrait. Topkapı Palace Museum, Istanbul, Turkey.

More often than not, over the next forty-five years, the sultan could be found at the head of his armies. In 1522, after five months of siege, Süleyman subdued Rhodes, the Christian base of piracy in the Mediterranean. Four years later, Süleyman led a major invasion of the kingdom of Hungary, on 29 August fighting the decisive battle of Mohács in which the Hungarian king Louis II (1516–1526) was slain and his countrymen utterly defeated. Between 1528 and 1529, Süleyman led his victorious armies into the

heart of central Europe and lay siege to the Habsburg capital of Vienna. This marked the furthest extent of Süleyman's advance into Christendom. Far from their depots of supplies and confronted by unexpectedly stiff resistance, Süleyman's forces withdrew to Istanbul, but Süleyman was undeterred in his dream to become "Lord of the Age."

The Ottoman Empire's other great rival in the world was the Safavid Empire of Persia. The Safavids had adopted Shiite Islam as their state religion, their messianic mission clashed with the Sunni Islam of the Ottoman Empire. Süleyman invaded Safavid territory and in 1534 captured Baghdad and most of Iraq. Southern Yemen fell in 1539, and in 1546 the sultan's armies captured Basra, in southern Iraq. The Shiite tribes in the south of Iraq stubbornly resisted the Ottomans, however, and the region was never completely subdued. Meanwhile, renewed war with the Habsburgs continued to preoccupy Süleyman to the end of his reign. In 1565 Süleyman unleashed his forces on the Christian stronghold of Malta; the ensuing siege failed disastrously at the cost of between twenty thousand and thirty thousand men. The next year, Süleyman died leading an Ottoman army in yet another campaign against the Habsburgs in Hungary.

The most famous and lasting achievement of Süleyman's reign, the creation of a single legal code for the entire Ottoman Empire that reconciled Islamic law with the law of the sultans, was not actually the work of Süleyman himself, but was the accomplishment of a legal expert named Ebu's-Su'ud Efendi. In the decades that followed the fall of Constantinople in 1454 and throughout the early sixteenth century, Islamic legal experts had slowly codified the laws of the sultans. By the time of Süleyman, this work was nearly completed, and sultan laws had been mostly regularized and replaced the many local laws and customs of the empire. The great problem was how to reconcile Islamic law with the legal code of the sultan. As a high-ranking judge, Ebu's-Su'ud used his authority to issue a *fetva* (fatwa)—"a proclamation issued by a qualified religious authority in response to questions of law and usage" (Goffman 2002, 76)—to

bring the two codes of law into harmony. Ebu's-Su'ud also added the title of caliph, meaning leader of the entire Islamic community, to the many titles of Süleyman, making the sultan the ultimate religious authority for all Muslims.

In Islamic tradition, Süleyman the Lawgiver will always be remembered as the “second Solomon,” a monarch who embodied a perfect concept of justice in accord with the Qur'an. His reign marked a period of justice and harmony for those of the Islamic faith.

Sumerian Civilization

In about 3500 BCE, inland and seafaring networks converged in Sumer (today's southern Iraq); the exchange of goods, information, and ideas gave rise to Earth's first civilization. Sumerians invented writing in a script we call cuneiform, but other innovations were incalculably significant, such as a simplified concept of gods inhabiting statues sculpted in human form, and fulltime soldiers equipped and trained for battle.

The Earth's first civilization arose in the land of Sumer beginning about 3500 BCE. Sumer was located in the southern part of modern Iraq where the Tigris and Euphrates rivers converge and flow through desert landscapes to the Persian Gulf. Irrigation was necessary to make the desert fertile; but that was comparatively easy since both rivers accumulated silt in their beds when crossing the flat desert between higher banks of silt deposited in flood time. Consequently, during most of the year, the water levels of both rivers stayed above the plain, and by digging through the raised bank water would flow through irrigation canals and smaller ditches onto adjacent fields. When enough water reached the fields, wheat and barley grew luxuriantly in the fertile soil, allowing dense human populations to flourish as long as they maintained the irrigation channels by the cooperative effort of thousands of persons.

Connecting Seafaring and Inland Networks

Dependable and abundant harvests were essential for the support of the city dwellers who planned and supervised irrigation and the distribution of water to

the fields. But the rise of Sumerian cities and civilization depended also on far-reaching exchanges of goods and information with peoples round about. Geography made Sumer a meeting place, where seafarers sailing along the coasts of the Indian Ocean and around Arabia into the Red Sea met overland donkey caravans and boats descending the Tigris and Euphrates rivers. Shipping along Indian Ocean coastlands preceded the rise of Sumer by thousands of year, and Sumerian tradition affirmed that they arrived in the land of Sumer by sea from somewhere in the south, and then organized irrigation agriculture among "the black headed people" already living there. But when their distinctive civilization began to emerge, donkey caravans were still comparatively new, since donkeys were domesticated only about 1,500 years before Sumerian cities began to thrive. It took time to breed enough donkeys to carry goods across hundreds of miles and an even longer time to convince local inhabitants that it was profitable for them to permit caravans to travel cross-country without being robbed.

But when this was achieved by about 3500 BCE a new web of communication came on stream, connecting peoples along the shores of the Indian Ocean and Red Sea with inhabitants of west Asia as far west as the Mediterranean coast, north to the steppes and east into modern Afghanistan. Precious goods, as well as new ideas and skills, started to circulate throughout the whole region faster than ever before; and Sumer was the place where everything new and valued converged. No wonder then that this was where the world's first civilization took form across the next five hundred years. Nowhere else did such a seafaring network interact with a comparable inland network.

Like spiders at the center of a web, Sumerians were able to pick and choose whatever interested them; they began to invent new things, and some of their ideas and skills soon spread far and wide, influencing Egyptians, inhabitants of the Indus River valley and of the Eurasian steppe. A civilizing process thus set in, and all of humankind is now its heir.

Eventually the Sumerian style of irrigation, which allowed river water to evaporate in the fields year after year, made the soil so salty that grain could not grow and the land became a desert once more. (Egypt escaped such salting, for there the Nile flood brought a load of fresh silt to the fields each year; the water then drained away, carrying all the dissolved salt back to the Nile.) But until about 2350 BCE when Sargon of Akkad conquered the cities of Sumer and the Akkadian language began to supplant Sumerian as the common speech of southern Iraq, Sumerian priests, rulers, traders, soldiers, and farmers combined to create Sumerian civilization, and in due course transmitted that heritage to their successors in the land between the two rivers.

Cuneiform Script and Archaeological Finds

We know quite a lot about ancient Sumer because the Sumerians invented a durable form of writing, using a pointed reed to make marks on soft clay and then baking the resulting inscriptions. We call the script cuneiform. Akkadians wrote their language in the same way, and as familiarity with Sumerian speech

decayed they made long lists of Sumerian words paired with their Akkadian equivalents. In the nineteenth century archaeologists dug up thousands of these clay tablets and soon learned to read Akkadian because it was a Semitic language resembling Hebrew and Arabic; then they used the word lists to learn how to read Sumerian, just as Akkadian schoolboys

had done before them. Years of effort went into deciphering the Sumerian language, which has no known relatives. But by now experts can read Sumerian inscriptions with few uncertainties, and since thousands upon thousands of Sumerian texts have now been read we know a good deal about their society.

Other archaeological remains also tell their own story. Large mounds of mud bricks locate each of the dozen or so Sumerian cities, sheltering something like 10,000 to 30,000 persons, that arose along the banks of the two rivers between 3500 and 3000 BCE. But cuneiform inscriptions let us know how specialized priests played the key role in managing and elaborating everyday life in those cities, and it seems clear that priests from all the Sumerian cities exchanged ideas from the beginning. Their first great achievement was to simplify the spirit world, crowded by innumerable spirits inhabiting everything that

The inlaid pictures carved on the sound box of a harp (from Ur, circa 2600 BCE), depict a menagerie of creatures—including a dog with a dagger tucked in his belt. The University Museum, Philadelphia, Pennsylvania.

moved, by deciding that seven great gods—earth, sun, moon, sky, storm, fresh water, and salt water—exerted overarching authority over everything and everyone, for each human body had a spirit of its own that wandered off in sleep (as dreams showed), and departed permanently at death. These seven gods, the priests decided, met on the first day of each year to determine what the next year would bring. And since melting snow in the mountains often raised the two rivers high enough to overflow their banks, erase irrigation channels and even, in extreme cases, change their path to the sea, Sumerians had much to worry about. Obviously they needed priestly experts to serve and please the high gods and persuade them, on each new year's day, to preserve their civilization from disaster.

The way the priests set out to please the gods was to construct a home for one or more god in each city. They swiftly became monumental temples reaching toward the sky. In a magnificent room at the top they placed a statue in human form for each god to inhabit, and the priests made it their business to provide them with the most magnificent food, clothes, and amusement they could contrive, hoping that this would make the god eager and willing to reside permanently in the statue and protect the city. As the gods' special servants,

priests communicated daily with the resident god by prayer, and figured out his or her intentions by interpreting marks on the liver of sacrificed animals as well as by exact measurement of the movements of the sun, moon, and planets.

In fact, of course, disasters continued to occur, which only stimulated greater efforts to please the gods with rarer and more precious objects, grander temples and more elaborate worship. The process was unending, compelling the priests to expand the scale of irrigation agriculture to support the elaboration of temple rituals. They also managed flocks of sheep on grasslands and employed large numbers of persons to spin and weave fine woolen cloth to clothe the god and themselves. Temples also exported surplus cloth far and wide, exchanging it for timber, incense, metals, lapis lazuli and other valued objects lacking in the flood plain. Private families owned some of the irrigated land in Sumerian cities, but the temple estates were far larger than private holdings, and by endlessly seeking new rarities to please the gods, priests kept on expanding the range and scale of export and import.

This sculpted goat, made from gold, silver, lapis lazuli, copper, shell, red limestone, and bitumen, is one of the most famous objects excavated from the royal cemetery in the ancient Sumerian city of Ur.

The figure is frequently referred to as the "Ram Caught in a Thicket" because it conjures an image of the ram that Abraham found (see Genesis 22:13) to sacrifice to God in lieu of his son. The University Museum, Philadelphia, Pennsylvania.

It is probable that the priests modeled their ideas about the behavior of the seven great gods on the way Sumerian landowners in early times met to garner public support for a call to action, whether mounting a military expedition to cut timber, building a new canal, or erecting a wall to defend their city against rivals close at hand and/or raiders from afar. For as Sumerian wealth and population grew, cities began to quarrel over access to the life-giving water needed for irrigation, while pastoral raiders were tempted to seize grain and other goods by force instead relying on peaceable trade.

Military Might

By about 3000 BCE, the rising importance of defense against human enemies provoked the construction of massive city walls, and military commanders, initially appointed for a single campaign, gradually made their authority permanent. Eventually they commanded armies of professional soldiers, equipped with bronze weapons and armor, trained to keep in step and present a formidable shield wall to the enemy. Not surprisingly, military leaders sometimes clashed with priests over how to manage the cities. An uneasy alliance between priests and military men became normal. Over time military power predominated; but collaboration and occasional clashes of warriors with religious experts and devotees have continued to affect subsequent civilizations all the way down to our own time.

The enhanced role of military leadership in Sumer coincided with the rise of tribal and pastoral society on the grasslands of western Asia. Sheep and goats predominated on semi-arid fringes of the Tigris-Euphrates Valley, but on the vast northern steppe, cattle and horses began to sustain a far more formidable military society. In the foothills independent agricultural villages soon found themselves caught between civilized armies and mounted steppe raiders, but to begin with the accomplishments of Sumer towered so high that Indo-European-speaking pastoralists on the steppes borrowed elements of Sumerian religion. As a result, Aryan, Greek, Roman, Celtic, and Germanic

gods of later times clearly resembled their Sumerian prototypes.

Beginning with Sargon of Akkad (c. 2350 BCE), military power tended to move north within the Tigris-Euphrates Valley as Semitic-speaking peoples mastered the arts of irrigation and other civilized capabilities. A long succession of territorial empires overran the once independent Sumerian cities until by slow degrees salt accumulated in the soil and their fields were abandoned. Thus the birthplace of civilization became a desert once again, yet the civilizing process initiated by the cities of Sumer continued to extend its range and power.

Significant Contributions

A brief list of Sumerian accomplishments will show how significant their contribution to subsequent human history turned out to be. Writing was Sumer's greatest invention. It transformed record keeping and allowed accumulation of knowledge and coordination of effort beyond what unaided human memory permitted. In addition, copper and bronze tools and weapons, wheel-spun pottery, and cunningly incised cylinder seals used to imprint marks of ownership on jars for shipping and storage first appear, and may have originated, in Sumer.

Canals, dikes, plows, wheeled vehicles, and sailing ships also show up in Sumerian records for the first time, but some or all of them may have been invented elsewhere. Nevertheless, Sumerians spread these fundamental improvements far and wide. When new, Sumerian temples were by far the largest and most impressive buildings in the world, and the Egyptian pyramids, that eventually exceeded them in size, began with smaller structures modeled on the Sumerian example.

Finally, the Sumerian invention of a family of gods inhabiting statues sculpted in human form, each in charge of an aspect of nature and accessible to priestly experts through ritual and prayer, was an immensely persuasive notion that spread very widely and dominated the religions of Europe and west Asia until Judaism, Christianity, and Islam eventually

superceded it. Moreover, full-time soldiers, systematically equipped and trained for battle were another Sumerian invention of incalculable importance in later times. Our world, in short, would not be as it is without the pioneering achievements of ancient Sumer.

Sun Yat-sen was a revolutionary leader and founder of Republican China (1912–1949). An uprising in 1911 resulted in his election as provisional president of the new republic and the abdication of the Qing dynasty emperor in 1912. Sun devised what he called the “Three People’s Principles” for the new republic: nationalism, democracy, and livelihood. Those principles are today the guiding ideology of the Republic of China on Taiwan.

Sun Yat-sen was the most prominent figure in the movement that overthrew the Manchu Qing dynasty (1644–1911/12) and established the Republic of China; he was also the founding leader of the Chinese Nationalist Party (Guomindang). Sun was born in Xiangshan County in Guangdong Province. After beginning his education in China, Sun was sent in 1879 to live with his elder brother in Hawaii, where he learned English while attending the missionary-operated Iolani School. After returning to China, Sun pursued European medical training in Guangzhou (Canton) and in Hong Kong, but quickly put aside his career as a doctor to focus on politics. Qing China had been subject to humiliating unequal treaties since the two Opium Wars (1839–1842 and 1856–1860) and now appeared increasingly vulnerable in an age of aggressive Western imperialism. In 1894 Sun traveled to Tianjin and petitioned the powerful official Li Hongzhang to undertake rapid reforms to modernize China. Li did not respond. Defeat in the Sino-Japanese war followed soon after.

Having failed to promote reform from within, Sun began to work for the overthrow of the Qing dynasty. He returned to Hawaii, and created the Revive China

Society to promote revolution. Most of his support came from fellow Guangdong natives, some of whom were members of secret societies that had long embraced an anti-Manchu ideology. In 1894 Sun’s first attempt at organizing a revolt in Guangzhou was foiled by Qing authorities. Sun fled to Hong Kong to avoid arrest. Forced to leave by British authorities, Sun proceeded to Japan, Hawaii, and the west coast of the United States trying to raise funds and gather support. While visiting London in 1896 Sun became the subject of a bizarre international incident in which he was held prisoner in the Chinese legation. Sun was able to get word of his captivity to friends, who brought his predicament to the attention of the press. When Sun was released he became an instant celebrity.

Over the next fifteen years Sun tirelessly promoted the revolutionary cause. Unable to return home, he traveled among overseas Chinese communities in Southeast Asia, Japan, and North America to raise funds and support. After 1900 he was introduced to young Chinese intellectuals in Japan sympathetic to the revolutionary cause, extending his connections beyond his original Guangdong base. In 1905 Sun published a newspaper editorial declaring that China needed nationalism, democracy, and government promotion of peoples’ livelihood. Repackaged as the Three People’s Principles, these became the centerpiece of Sun’s revolutionary ideology; he repeatedly redefined these terms over the next two decades. In 1905 Sun became the director of the Chinese Revolutionary Alliance, which brought together a diverse group of supporters of revolution.

Initially, the expatriate revolutionaries made little progress as the Qing dynasty struggled to remake

Bust of Sun Yat-Sen. Sun became an icon celebrated for his tireless patriotism and his focus on a strong, modern China. Photo by Joan Lebold Cohen.

itself in the early years of the twentieth century. But when governmental reforms stumbled after 1908, the revolutionaries gained a growing following in China. Nevertheless, when the Wuchang army garrison rose up in October 1911 to spark the revolution, it was a surprise. Sun Yat-sen was in the United States, and rather than returning to China directly, he headed to Europe to seek foreign support for the revolutionary cause. Upon his arrival in Shanghai in late December he was greeted as a hero by the revolutionary forces, now in control of major cities in central China. On 1 January 1912 Sun was sworn in as the provisional president of the new Republic of China.

But Sun's triumph was short-lived. The revolutionary forces negotiated an end to the war with Yuan Shikai (1859–1916), a Qing official with a record

as a reformer and strong support from the powerful northern army. Sun resigned the presidency and supported the selection of Yuan as his replacement. The Revolutionary Alliance was remade into a democratic political party, and renamed the Nationalist Party. Led by Song Jiaoren (1882–1913), the new party won victory in assembly elections in 1913. But Yuan refused to become a figurehead: he arranged Song's assassination and in the "second revolution" drove Sun and his supporters out of government and established a dictatorship. Yuan's subsequent effort to establish himself as emperor failed miserably, Beijing's authority collapsed, and power was divided among regional warlords.

Sun Yat-sen tried desperately and unsuccessfully to restore his vision of a unified Chinese republic from

The Revolution has not yet succeeded. Comrades, you must carry on! • Sun Yat-sen (1966–1925)

Portrait of Sun Yat-Sen. Sun called the ideals he advocated for China's new republic the **Three People's Principles: nationalism, democracy, and livelihood.**

1914 to 1920. Frustrated by foreign support for Yuan, he turned to Japan, and offered major concessions in return for Japanese support, without success. After Yuan's death, Sun sought to restore the 1912 constitution, but the warlords would not cooperate.

In the early 1920s Sun began to establish a political base in Guangzhou and to reconstitute the Nationalist Party. In 1922 he sought out the aid of Comintern, the association of national Communist parties founded by Vladimir Lenin (1870–1924), in reorganizing the Nationalist Party on a disciplined Leninist model. Sun, while admiring the successes of Lenin, never embraced Marxism. Sun's own Three People's Principles—now taking on an increasingly socialist and anti-imperialist flavor—formed the ideological orthodoxy of the renewed Nationalist Party.

Meanwhile a United Front was formed with the fledgling Chinese Communist Party, and a talented cadre of young Nationalist and Communist leaders, including Chiang Kai-shek (1887–1975) and Zhou Enlai (1898–1976), came to Canton. Sun, now convinced that his vision could only be fulfilled by a strong army, formed a military academy and began to train an army for the planned northern expedition to destroy the warlords and unite the country.

In January 1925, Sun made one last effort at a peaceful unification, traveling to Beijing at the invitation of northern warlords Duan Qirui (1865–1936) and Zhang Zuolin (1873–1928). Before these talks could produce results, Sun fell ill with cancer, and he died on 12 March.

Sun's death deprived him both of seeing the success of the Northern Expedition and the end of the warlord era and of witnessing the bitter break between Chiang Kai-shek's Nationalists and the Chinese Communist Party. As a result Sun has a unique role in the symbolism of modern China: admired across the political spectrum, he became an icon celebrated for his tireless patriotism and his advocacy of a strong, modern China. Historians' assessments of Sun have varied. While Chinese scholars often treat Sun as a near sacred figure, Western scholars have been less admiring. Critics view Sun as a symbolic rather than as a substantive figure, as a man who advocated change but was rarely in a position to execute it. But Sun's role in linking China with overseas Chinese communities and his advocacy of technocratically oriented models of industrial development seem prophetic of China's place in the globalizing world that has emerged since the end of the Cold War.

Taiping Rebellion

Spurred and initially led by Hong Xiuquan, the Taiping Rebellion (1851–1864) seriously challenged China's Qing dynasty (1644–1911/12). Millions of lives were lost in the ensuing chaos. As the largest rebellion in Chinese history, it was a catalyst for the first reform movement launched by the Qing in an attempt to modernize the empire, a process the Qing had resisted for some time after its clash with Western powers in the First Opium War (1839–1842).

The Taiping Rebellion occurred in a period of unprecedented crisis, when the Qing dynasty was plagued by an exploding population (nearly tripling in two centuries to exceed 430 million by the 1850s), political and social problems, and challenges from Western powers that it could not meet, as evidenced in its defeat in the First Opium War (1839–1842). With the city Guangzhou (Canton) becoming one of the five ports opened to international trade, as stipulated by the Treaty of Nanjing (1842) at the conclusion of the that war, Western influence became increasingly tangible in the city and its surrounding area, though missionaries, including Protestant missionaries from the United States, had been arriving in China's southern coasts before the Opium War. Meanwhile, the opening of Shanghai as one of the treaty ports undermined Guangzhou's position as the sole hub of international trade in China. As a result, many laborers who had been hired by foreign trade-related businesses in the Guangzhou area lost their jobs, which contributed to worsening social problems that had accumulated in southern China.

The Origins

Hong Xiuquan (1814–1864), born to a peasant family of the Hakka ethnic group in a village close to Guangzhou, was raised to pursue a career as a scholar-official. Having repeatedly failed to pass the civil service examinations in Guangzhou, Hong suffered a breakdown in 1837 and was bed-stricken for weeks, during which he had hallucinations. A few years later he read a set of Christian tracts, *Quanshi Liangyan* (Good Words for Exhorting the Age), which was compiled by a Chinese Christian, Liang Afa (1789–1855), and delivered to Hong's hand after he failed examinations in Guangzhou in 1836 by an American missionary, Edwin Stevens (1802–1837). Hong made connections between Christian theology and his visions and was convinced that he was actually Jesus Christ's younger brother, and that he was sent to Earth to expel demons, namely the Manchus (who ruled China during the Qing dynasty), from China.

Having baptized himself and a few friends and relatives, Hong began his evangelical mission in his home village. In early 1844, along with one of his converts, Feng Yunshan (1822–1852), Hong went to Guangxi Province after having lost his teaching post at the village school due to his Christian convictions. In the poverty-stricken southern Guangxi, Hong and Feng found enthusiastic adherents among poor peasants. Later in 1844, Hong left the evangelic work to Feng and returned home to continue his religious study for a couple of years (during which time he had a short sojourn in Guangzhou to study with an American missionary, Issachar T. Roberts [1802–1871]); Hong

A drawing of the Taiping leader Hong Xiuquan ("The Heavenly King") circulated by Taiping propagandists in the 1850s. From *A Yankee Adventurer: The Story of [F. T.] Ward and the Taiping Rebellion* by Holger Cahill (1930).

then penned several religious tracts to expound his own understanding of Christian faith. When Hong rejoined Feng in Guangxi in the late 1840s, Feng had set up a religious community of thousands in the Zijing Mountain area. With the expansion of their community and the heightening of the tension with the Qing local authorities, Hong and his followers proactively prepared for an armed uprising.

The Early Stage (1851–1856)

In late 1850, Hong called for a rebellion against the Qing dynasty. He proclaimed the establishment of Taiping Tianguo (the Heavenly Kingdom of Great Peace) in January 1851 and declared himself the Heavenly King shortly thereafter. The Taipings, as they become known in English, set up an elaborate military system in which men and women were segregated and forced to submit all their properties to a public treasury. After having stayed in the city of Yong'an in eastern Guangxi for half a year to rigorously undertake state building and militarization, the Taipings began to march north to the Yangzi (Chang) River valley in 1852. The Qing armies, which had not been engaged in serious fight for decades, failed

to stop the advances of the spirited Taipings. In the spring of 1853, the Taipings, then in the hundreds of thousands, took Nanjing, a political and economic center in southeastern China. Hong made Nanjing his capital and renamed it Tianjing (Heavenly Capital).

After taking Nanjing, the Taipings moved quickly to expand their military victories. A northern expedition was dispatched to take Beijing, the capital of the Qing dynasty, and a western expedition was sent to take control of the middle Yangzi River valley and secure the areas surrounding Nanjing. Although the northern expedition failed, the Taipings were successful in expanding their territories in the middle and lower Yangzi River valleys. Administrative apparatuses were set up on the conquered territories, which combined military and civil functions. A utopian land program blueprinting equal distribution of land was promulgated, but never implemented. Many social and cultural reforms—including banning opium smoking, foot binding and prostitution—were carried out. Repudiating Confucianism as the demon's teaching, the Taipings adopted Hong's version of Christianity as their official religion and used it as the basis for their civil-service examinations, in which both men (and very recently women) were encouraged to participate.

The Taipings' claim that they believed in Christianity stirred great excitements among the Western missionaries while the prospect of an extensive civil war worried the Western businessmen in China. Both groups urged their countries' diplomats to take actions and go to the Taiping capital for a close examination of the rebels. In 1853 and 1854, Britain, France, and the United States sent envoys to Nanjing to investigate the new regime. Although the Westerners were deeply disappointed by the Taiping religion, which they thought was a great distortion of Christianity, and by the rebels' lack of commitment to order and construction, the Western powers decided not to act against the Taipings immediately because they had not settled their conflicts with the Qing government. As a result, they adopted temporary neutrality toward the rebellion, but their overtone betrayed their hostility against the Taipings.

"The Taiping War in China: Costumes of Imperial Mandarins and Soldiers."
From the *Illustrated London News*, 1864.

When the Taiping Rebellion reached its peak in 1856, fatal infighting occurred. Threatened by the swelling power of Yang Xiuqing (d. 1856), the de facto prime minister of the Taiping regime, Hong had him killed by another leader, Wei Changhui (1823–1856). Later Hong also had Wei killed when the latter could not stop his indiscriminate slaughtering of Yang's followers. Tens of thousands of Taiping followers were slain in the incident. Feeling that he was no longer trusted, Shi Dakai (1831–1863), a talented and popular general, led his army out of Nanjing and carried on an independent campaign until he was cornered by the Qing forces at the Dadu River in western Sichuan in 1863, where he surrendered (and was subsequently executed).

The Late Stage (1856–1864)

The Taiping Rebellion was greatly weakened by the events of 1856 and by losing much territory to the Qing armies in the wake of the incident. Meanwhile, the Qing dynasty found a powerful force in suppressing the rebellion, the Xiang (Hunan) army led by Zeng Guofan (1811–1872), a high official and famed Confucian scholar. Zeng commanded strong support among the gentry class by upholding Confucian values in countering the Taiping form of Christianity.

Recruited exclusively from Zeng's hometown in Hunan Province and highly paid and well disciplined, the soldiers of the Xiang army pushed the Taipings into a defensive position. Two new leaders and outstanding generals of the Taipings, Li Xiucheng (1823–1864) and Chen Yucheng (1837–1862), orchestrated a series of successful campaigns to break the impasse, advanced to eastern Jiangnan, and approached Shanghai, an important treaty port since the First Opium War. Hong Xiuquan's cousin, Hong Ren'gan (1822–1864), arrived in Nanjing after having stayed in Hong Kong for years, breathing new life into the waning regime by attempting to reform the Taiping political and economic systems by using Western models. Although Hong Ren'gan's reform agenda did not materialize due to the severe military situation in the last phase of the Taiping Rebellion, his ideas were echoed by reformers in the latter part of the nineteenth century. Having finally made his way to Nanjing, Issachar T. Roberts failed to convince Hong Xiuquan, who had by then lost touch with reality and was immersed in his illusionary world, to rectify his religion. Roberts left Nanjing in early 1862.

From 1856 to 1860, the Qing dynasty was engaged in the Second Opium War (also known as the Arrow War) with Britain and France. Disappointed with the Qing noncommittal attitude toward fulfilling the

Battle action near Shanghai between the mercenary forces of the Ever-Victorious Army, led by Frederick Townsend Ward and the Taipings.

treaty obligations after the First Opium War, Britain set higher goals for the second conflict. After the four-year war punctuated with truce and negotiation, Britain and France landed new treaties that gave the powers more rights including stationing their ambassadors in Beijing and more treaty ports including Nanjing and several other cities in the war zone, which made the Taiping regime an indisputable obstacle to the implementation of the treaty benefits. Shortly after the conclusion of the Second Opium War, a coup d'état occurred that placed a new rulership on the stage for the Qing. The new leaders, the Empress Dowager Cixi (1853–1908) and Prince Gong Yixin (1833–1898), effected a radical turn in foreign policy, becoming cooperative with the West, which encouraged the Western powers to side with the Qing dynasty in China's civil war. Having realized that it was best for Britain's long-term interest in China to leave the Qing dynasty as the ruling regime, Sir Frederick Bruce (1814–1867), the British envoy extraordinary and minister plenipotentiary to China, authored a policy of indirect intervention in China's civil war, by which the Western powers should assist the Qing dynasty in its campaign against the rebels, and at the same time entice the Qing dynasty to strengthen and modernize its governmental apparatus and functions.

In late 1861, Li Xiucheng and his men carried out an eastern expedition, taking both Ningbo (it became a treaty port after the First Opium War) and Hangzhou, and prepared to attack Shanghai. The Taiping threat to the eastern coast area, where Western commercial interest was heavy, served as the fuse

to the onset of Western intervention. The first clash between the Western powers and the Taipings took place in early 1862 when Li attacked Shanghai. After that the Western intervention took shape with foreign mercenaries, the so-called Ever-Victorious Army, financed by the Qing government and headed first by Frederick Townsend Ward (1831–1862) of the United States and then by Charles George Gordon (1833–1885) of Britain. Meanwhile, the leaders of the Xiang army also actively acquired Western weaponry and hired Western military advisors. After 1862, the Taipings retreated city by city under the joint attack of the Xiang army and the Ever-Victorious Army. In June 1864, Hong Xiuquan died of illness. One month later, the Xiang army captured Nanjing, which ended the Taiping Rebellion, even though the remaining Taiping forces continued to fight until 1868.

About 20 million lives were lost in the extensive warfare associated with the Taiping Rebellion and other rebellions of the period. Economic devastations in the lower Yangzi River valley were extensive. While Taiping Christianity failed to leave any lasting impact on Chinese society, the Qing dynasty tried to bring about a restoration of Confucian tradition in the wake of the upheaval. Meanwhile, reform-minded high officials including three major generals rising to power in the campaign against the Taiping Rebellion, Zeng Guofan, Li Hongzhang (1823–1901) and Zuo Zongtang (1812–1885), pushed the Qing to take the first step toward modernization: the Self-Strengthening Movement (1861–1895), which placed an unequivocal emphasis on adopting Western military technology.

Holding the Universe in the hand, I slay the attacking powers. • **Hong Xiuquan**
(1814–1864), from “The Poem on Executing the Vicious and Preserving the Righteous”

In the rest of the nineteenth century, the British policy that had taken shape during the Taiping Rebellion—assisting and strengthening the Qing—continued to serve as Britain’s China policy, resulting in a different form of imperialism in China than in India and some other parts of Asia, where the British Empire ruled as a colonizing power in its own right.

Tang Taizong

(599–649 CE)

SECOND EMPEROR OF CHINA'S TANG DYNASTY

Emperor Taizong of the Tang dynasty (618–907 CE) was a benevolent ruler who created perhaps the greatest administration in Chinese history. He encouraged people to criticize his policies, he established a bureaucracy based on merit, and in foreign affairs he built alliances and won allegiance by fair treatment.

Emperor Taizong (reigned 626–649 CE) of the Tang dynasty (618–907 CE), hailed in Chinese history as exemplifying the ideal Confucian rule of benevolence and righteousness, established a cosmopolitan empire and facilitated the spread of culture and trade in East, Central, and Southwest Asia and beyond. The effective administration and prosperity of his reign lay the foundation of a strong Tang dynasty; his empire extended to the steppes, and he controlled the Silk Roads in Central Asia.

The Empire

During Taizong's reign, Chinese government, laws, and culture (including Confucianism, poetry, and architecture) spread to other East Asian states and was incorporated into the local culture. Japan's Taika Reforms (from 645), in which the Japanese court adopted a Chinese-style centralized government, system of taxation, and law code, is one example. Unlike rulers of later dynasties, Taizong also embraced cultural diversity. While adopting Confucianism as state guideline, he also honored Laozi and Daoism, supported Xuanzang, the great monk who made a pilgrimage to India to translate Buddhist sutras into Chinese, and built a Nestorian Christian church along with Zoroastrian temples in Chang'an, the

capital city. Chang'an, magnificent in appearance and culture, attracted foreign envoys, traders, and clerics who traveled there along the Silk Roads and by sea. People from all over Asia and even Africa, including the Turks, Persians, Arabs, Japanese, and Koreans lived among the Chinese in Chang'an and in southern port cities. Their food, clothing, arts, and the religion of Buddhism became part of the Tang culture, while Chinese silk, goods, and technology spread to the other lands.

The Emperor

Tang Taizong (the emperor's reign title; his birth name was Li Shimin) came from an aristocratic family from northern China. His mother and his wife were both of non-Chinese descent but they were known for Confucian propriety and were skilled in Chinese literature and calligraphy. Shimin was the second son of Li Yuan, a provincial governor under the Sui dynasty (581–618). In 617 Li Yuan rebelled against the unpopular Sui emperor Yangdi. Modern historians questioned the traditional account of Shimin's pivotal role leading to the uprising, but all agree that in the next four years Shimin defeated various contenders for the throne. At age twenty-four, he secured the empire for his father, whose warfare established the Tang dynasty.

Shimin excelled in cavalry and was an excellent strategist and commander. His exceptional achievements, however, led to fierce rivalry with his elder brother, who was the crown prince, and with his younger brother. In 626 Shimin triumphed over both brothers, who were killed, and ascended the throne at the age of twenty-nine as Tang Taizong when Li Yuan retired.

Yan Liben, *Emperor Taizong Receiving Tibetan Envoy*. Ink and color on silk. The Tibetan envoy is second from the left. Female attendants surround the emperor on the right. The Palace Museum, Beijing.

Bureaucratic Policies

Shimin inherited a war-torn economy from over a decade's fighting amongst rival forces since the end of the preceding Sui dynasty. To rejuvenate a land devastated by wars, Taizong adopted benevolent policies. He distributed land to farmers and collected taxes accordingly (approximately one-fortieth of income), and in kind. He was frugal in his expenditures and adopted a conciliatory foreign policy in his early reign to avoid wars. Taizong also ordered the revision and compilation of a penal code; the revised code reduced cruel punishments and became the foundation for later Chinese penal codes.

Tang Taizong also established a bureaucracy based on merit, responsible officials, and thoughtful policy (state policies were prepared and reviewed by different offices before implementation). He discussed policy with chief ministers, appointed officials and generals based on their ability, regardless of class, ethnicity, or personal connections, and he held civil-service exams with questions based on the Confucian classics. Many of his most accomplished and devoted officials and generals had been on the staff of his former enemies or rivals. Independent examiners regularly reviewed

officials; the emperor tolerated no abuses even from his own kinsmen.

He also encouraged criticism of any of his policies or behavior that people judged inappropriate. His most outspoken critic was Wei Zheng (580–643), who had once served one of the emperor's brothers. It was not always easy for a powerful and highly accomplished monarch to hear disagreement, frank criticism, or interventions, but the emperor restrained himself and rewarded his critics when their arguments were reasonable and sound. He kept Wei Zheng at his side and referred to him as his mirror that allowed him to see his mistakes. In fact, he credited Wei Zheng and other officials for making him a good ruler.

By 630, the fourth year of his reign, which the Chinese called the "Fine Governance of the Zhen-guan," official Tang dynasty histories compiled by court historians of later dynasties recorded this scene of prosperity: "The price of the grain was cheap. Cows and horses grazed freely in the field, people did not lock their outside gates, and there were few people in the jail. Merchants were no longer bothered by the bandits, the powerful families no longer dared to threaten the small people and in some regions people did not need to bring provisions when traveling

because they receive the hospitality of the people on the road” (Liu 1975, 3.41).

Frugality and Virtuous Customs

Besides sound policies and practices, prosperity was also achieved through frugality by the state and among the people. Tang Taizong was not only frugal in government expenses, but he also prohibited imperial clansmen and officials from extravagance in dwellings, carriages, and clothing. Concerned with luxurious and wasteful practices, he issued an edict to ban elaborate weddings and funerals among nobles and commoners. Tang Taizong blamed extravagance and indulgence for the fall of bad rulers throughout history, including Yangdi of the preceding Sui dynasty. He believed that “calamities derived from lascivious desires,” and “if arrogance and luxurious indulgence were unchecked, one can expect danger and destruction in no time” (Wu 1965, 1.1, 3.185). He also reminded his officials that taking bribes caused their eventual downfall and destroyed both their personal and their professional reputations. In *Difan*, an instruction manual for rulership that he prepared for his heir, Tang Taizong devoted two of the thirteen chapters to rail against luxury and indulgence, considering frugality essential for a good and lasting state. Therefore, throughout his more than twenty-year reign of during Zhengguan, the state was strong and prosperous, the customs were pure and simple, there were no embroidered robes or fine linen, and there were no problems of hunger or shortage of clothing.

The Confucian Goal of Life

Some of Tang Taizong’s trusted officials, such as Wei Zheng, Wen Yanbo, Chen Wenben, as well as the emperor himself, especially in his early reign, lived modestly, despite their power, wealth, and high positions. In what did they find joy, and what did they strive for in life? Tang Taizong once commented that the price of grain was low and people had surplus; this general prosperity gave him great pleasure even as he

refrained from his favorite hunting trips. *Zuo Zhuan*, one of the well-known commentaries for Confucian’s book, the *Spring and Autumn Annals*, described the three works that gave an individual everlasting existence or immortality—to manifest great virtue, to make great contributions (to all under heaven) or to leave works or writings of enduring value. Instead of treasuring material possessions or the perpetuation of one’s physical life, the Confucian work exhorts the individual to strive for a lasting legacy by bettering the lives of others with memorable deeds, words or virtue.

Tang Taizong was well versed in Chinese classics, and he frequently studied and discussed them with his officials. His officials could also recite Confucian values by heart because they engaged in the extensive review and compilation of commentaries for the five Confucian classics to prepare a standard version for the civil service examination. Tang Taizong’s political achievements were also complemented by a cultural spirit that valued virtue, public well-being, and works of wisdom. These Confucian goals have helped to produce many fine administrators in Chinese history as well as a large number of fine writings that have been preserved with great effort for later generations.

Stable domestic development was also connected to the alleviation of external threat. The statement about from the Tang court histories about peace and prosperity quoted above was also realized because of the defeat of the Tujue (Turks in Mongolia) in 630.

Foreign Affairs

In foreign affairs, Taizong preferred alliances and winning allegiance through the appeal of fair and kind treatment, but he used military force when necessary. In 630 he dispatched troops and defeated the eastern Turks (in modern Mongolia), who often raided Tang cities and were the serious threat of the Tang dynasty. In the following years his army conquered more territory, but more importantly, it secured the submission of tribes and kingdoms in central Asia and around the Silk Roads without wars. Often, Taizong offered Tang princesses in marriage to tribal leaders to forge

Li Shimin (Tang Taizong), *Encomium on the Warm Springs* (628 CE). The emperor, an avid collector of calligraphy by the master Wang Xizhi, practiced the art himself.

friendly diplomatic relations. When leaders submitted to Tang rule, Taizong made them governors of the regions they had formerly ruled independently, and he rarely intervened in their affairs. He allowed migration and in some instances ransomed back nomad clansmen who had been seized by their enemies. While considering weapons as unfortunate instruments that should not be used often, Tang Taizong nevertheless considered it important to maintain an adequate arsenal to protect the state.

Arts and Culture

Taizong loved fine horses, but he was also well versed in poetry and was an accomplished calligrapher. He ordered the compilation of the five Confucian Classics,

as well as a commentary on them, and these became the standard texts for later dynasties. He wrote a preface for Xuanzang's monumental translation of hundreds of Buddhist sutras and ushered the robust development of Buddhism during the Tang dynasty. Tang Taizong engaged his officials to undertake the writing of the official history of the previous dynasties, and he also wrote three commentaries in these works. He revered Daoism and claimed its legendary founder Laozi, whose family name was Li, as his royal ancestor. His broad interest and open attitude set the tone for a cosmopolitan and vibrant Tang culture.

Legacy

When Taizong died in 649, he was buried in Zhaoling, on a majestic mountain, which eventually was home to a constellation of over 160 tombs. Some of these were the resting places of imperial relatives, but most of the tombs housed meritorious officials, including over a dozen nomadic generals: Taizong had granted meritorious ministers the right to be buried in his mausoleum complex and included them in his extended political family.

Tang Taizong and his officials created a political legend in Chinese history. His recorded discussions with officials, the *Zhenguan zhengyao* (Essentials of Government of the Zhenguan Period) became part of the imperial curriculum for later Tang and all subsequent Chinese emperors, as well as for the rulers of Japan and Korea. It even influenced the non-Chinese Khitan, Jurchen, and Mongol peoples. Tang Taizong manifested the validity of Confucian benevolent rule, but he was also fully aware of the difficulties and complexity of governing a large empire. Throughout his reign, Tang Taizong and his officials remained vigilant, consciously preserving good rule and bequeathing it to their descendants.

Tea

Since its accidental discovery over ten thousand years ago in the jungle triangle that covers where the borders of Myanmar (Burma), Assam (in present-day India), and China meet, tea has become the most consumed liquid on Earth, apart from water. As a commodity and a beverage, tea has had immense consequences for almost every aspect of human life and international relations.

Tea is a drink made by picking and drying the leaves of a species of camellia, *Camellia sinensis*. The leaf is then infused in hot or boiling water. Tea has many advantages as a trade good. For one thing, it can be produced cheaply. The semitropical climate it prefers is found in geographic regions as widely separated as central China and East Africa. Only a few leaves are needed to make a good pot of tea, and they can be reused. Dry tea is very light and stores well, so it can be shipped across the globe with ease, and its high value in relation to its weight makes it worthwhile to do so.

The Spread of Tea

Tea moved from the jungles of the golden triangle into the gardens of China at least a thousand years before the birth of Christ. It spread across all of China by the eighth century CE. From the ninth century onwards it became the chief commodity traded with the wandering tribes of Central Africa. The Mongols and Tibetans became great tea drinkers, and blocks of tea became the local currency. Tea was drunk by Buddhist monks as a medicinal beverage in Japan from the eighth century; in the thirteenth century the habit

of drinking tea spread to the rest of the population, and tea became the universal drink.

Tea began to be imported to Europe in the seventeenth century. When the direct clipper trade to China opened up in the 1720s, the price dropped and

Kitagawa Utamaro's woodblock print (ukiyo-e), circa 1801–1804, shows a woman serving children at a tea party during Hinamatsuri (Girl's festival). Library of Congress.

Men read and engage in conversation at a Chinese tea shop in the late nineteenth century.

the imports soared. By the middle of the eighteenth century it was widely drunk by all classes in Britain. It was exported to the colonies, and the duty imposed on tea contributed to colonial unrest (as demonstrated in the Boston Tea Party of 1773, in which angry colonists dumped shipments of tea into Boston Harbor), which culminated in the American Revolution and the establishment of the United States.

The British Empire was to a considerable extent built around tea, and the British East India Company's profits were largely based on the tea trade and the three-way movement of opium, tea, and silver between India, China, and Britain. The British introduced tea into Assam from the 1840s, and by 1890 the region boasted large plantations and machine-based production in factories. Tea production continued to expand and spread, moving into southern India and Sri Lanka. The Indians themselves became great tea drinkers only from the 1920s. Before that almost all the tea had been exported to Britain, where it was sold for a higher price than it could fetch in India.

Because tea is best grown on plantations, its cultivation has altered the ecologies of the areas where it was grown, unsettled tribal populations, and thrown hundreds of thousands into boring, miserably paid labor, yet made huge profits for investors and tea managers. In Assam, for example, swathes of jungle, rare

plants and many animals were destroyed. The tea coolies were herded into factories and into sweated labor in the gardens. The conditions have slowly improved, but are still often deplorable.

Tea and Social History

Tea is easily prepared for drinking, but its preparation is sufficiently elaborate to encourage the human love of play and ceremony. In East Asia it had an enormous effect on social life through the tea ceremony, which drew on elements of religion (especially Daoism in China and Zen Buddhism in Japan) and had a profound influence on aesthetics in areas as diverse as ink painting, pottery, and architecture. The Chinese, Korean, Japanese, and British developments in porcelain and pottery, themselves highly important trade goods, were centered on tea bowls and other tea ware. In present-day Japan, mastery of the tea ceremony is considered a sign of good breeding, and the tea ceremony industry is quite large.

Drinking tea altered gender relations, meal times, and etiquette. It helped raise the status of married women in eighteenth- and nineteenth-century England. It made the English breakfast less meat-intensive and allowed the evening meal to be held later. It also led to new formal gestures of politeness and courtesy surrounding the preparation and serving of tea.

*Thank God for tea! What would the world do without tea? How did it exist?
I am glad I was not born before tea.* • Sydney Smith (1771–1845)

Nathaniel Currier, *The Destruction of Tea at Boston Harbor* (1846). Lithograph. Contrary to Currier's iconic depiction, few of the men dumping tea into the harbor were disguised as Native Americans. Library of Congress.

Today approximately three billion people a day drink tea. Long appreciated for the gentle stimulation its caffeine content provides, tea is also highly regarded for its ability to kill the microorganisms that cause many water-borne diseases, and it is highly touted for its antioxidants. Historically, it has affected politics and the relations between nations and empires. It encouraged the development of new types of ship and ingenious factory machinery; it funded great trading companies and inspired literature and philosophy. It is indeed a remarkable plant.

Technology— Computer

Humans have always looked for “technologies” to help them count—from stick-markings prehistoric foragers made to keep track of cattle to the first programmable, room-filling mainframes employed by post-World War II business. In the twenty-first century computers do far more than calculate; forecasters predict that the computing power of today’s desktop will someday be packaged in a device the size of a shirt button and for the cost of a dime.

Computers have transformed work, communication, and leisure activity, and they promise future changes of equal magnitude. For many years, computer technology was dominated by groups in the United States, because that nation had the largest single market and its government invested heavily in military applications and fundamental science and engineering. But many nations contributed to the technological basis on which computing arose, and with the development of the World Wide Web computing became a global phenomenon.

Mechanical Predecessors

Programmable digital computers were developed just before the middle of the twentieth century, but the more general history of devices that help people think goes back to prehistoric times, when someone first carved marks on a stick to count the cattle in a herd or mark the days in the phases of the moon. Complex additions and subtractions were done in ancient days by arranging pebbles in piles on the ground, and our word *calculate* derives from the Latin word *calculus* (pebble). The most complex known “computer”

of classical civilization is the remarkable geared Antikythera device, which apparently was designed to predict the motions of the sun, moon, and planets. Found in a shipwreck on the bottom of the Mediterranean Sea, it is believed to date from about 80 BCE.

Computing has always been closely allied with mathematics, and the invention of logarithms by the Scottish mathematician John Napier around 1614 was a major advance for practical calculating. With a mechanical calculating device, it is much easier to add than to multiply, and subtraction is much easier than division. Logarithms turned multiplication into addition, and division into subtraction, at the cost of looking up numbers in vast books of tables that also had to be calculated by hand. From Napier’s time until the introduction of transistorized electronic calculators around 1970, a book of logarithm tables was a standard tool for engineers and scientists. They were cumbersome to use, so for quick estimates slide rules were employed. A slide rule is an analog calculating device based on logarithmic scales marked along rulers that slide past each other. The term *analog* refers to the analogy between the abstract numbers and corresponding physical distances along a line.

Digital mechanical calculators that represented numbers as precise digits were also developed—for example, by the French mathematician and philosopher Blaise Pascal in 1642. A common approach was to connect a series of wheels, each of which would turn in ten steps for the digits 0 through 9. A legend has developed that the eccentric English dilettante Charles Babbage was the father of computing because around 1835 he designed a mechanical calculator that could be programmed with punched cards. Science fiction writers William Gibson and Bruce Sterling

Computers are useless. They can only give you answers.

• Pablo Picasso (1881–1973)

wrote a novel imagining that Babbage succeeded in building it, launching a golden age of British scientific and technological dominance but magnifying social problems. However, in reality Babbage failed, and historian Doron Swade estimates that his influence on the development of electronic computers was insignificant.

The first comprehensive digital data-processing system using cards was developed by the American engineer Herman Hollerith, who began patenting his ideas in the 1880s. By 1902, when his machines were used to process the vast sea of information collected in the 1900 U.S. census, they already incorporated electric relays that could do conditionals (if-then operations).

The Mainframe Era

There is considerable debate among historians over which programmable, electronic digital computer was first or most influential. By 1941, professor John Atanasoff and graduate student Clifford Berry had created a demonstration machine at Iowa State University, but they did not develop it further. In Britain, a special-purpose electronic computer called Colossus began cracking German codes in 1943, but its design was kept secret for more than three decades. Perhaps the most influential early electronic digital computer was ENIAC (Electronic Numerical Integrator and Computer), completed at the University of Pennsylvania in 1946 by a team headed by physicist John W. Mauchly and engineer J. Presper Eckert.

ENIAC's primary job was calculating accurate artillery firing tables for the U.S. Army. In the frenzy of World War II, many new models of long-range guns were being produced, and soldiers in the field needed complex tables to tell them how to aim to hit a target at a certain distance

under various conditions. It was impossible to fire the guns under all the likely conditions, so data from some judiciously chosen test firings were used to anchor elaborate sets of mathematical calculations. Vannevar Bush, who was the chief science advisor to President Roosevelt, had a huge mechanical analog computer, the *differential analyzer*, built for this purpose in 1930. In theory, an electronic computer would be much faster and more accurate, but there were serious questions about whether it could be sufficiently reliable, because before the development of transistors they were built with vacuum tubes that tended to burn out. ENIAC weighed 30 tons, covered 1,800 square feet, and contained 18,000 vacuum tubes.

ENIAC's data input and output employed Hollerith's punch cards, a method that remained one of the standard approaches through the 1970s. However, programming was done manually by setting hundreds of rotary switches and plugging in wires that connected electronic components. Mauchly and Eckert designed a successor that could store a program in its memory. They formed a small company, launched a line of machines called UNIVAC, and then sold out to a private company in 1950. This example typifies mid-twentieth-century computing. The technology for large and expensive mainframe computers was developed with government funding for military purposes and then transferred to the civilian sector where it was used by large corporations for financial record-keeping and similar applications.

Much of the research work was done at universities, and the availability of a few mainframe computers on campus gave scientists the chance to adapt them to many research purposes.

The Personal Computer

The birth of the computer industry involved nothing less than development of an entire computer culture, including programming languages and compilers to control the machines, networks and input-output devices to transmit information between users and machines, and new courses in universities leading to the emergence of computer science and engineering as a distinct field. For years, the dominant model was expensive mainframe computers with batch processing of data—computer runs that were carefully prepared and then placed in a queue to await time on the mainframe—although there were some experiments with time sharing in which several individuals could use a computer simultaneously in real-time. Then, in the mid-1970s, both inside information technology companies and outside among electronics hobbyists, the personal computer revolution offered a radically new concept of computing.

In April 1973, Xerox corporation's Palo Alto Research Center ran its first test of the Alto, the prototype

desktop personal computer. Alto innovated many of the technologies that would become standard for home and office computers, including the mouse, windows and icons on the screen, desktop printing with many different fonts, incorporation of images and animations, and local area networks that allowed individuals to send files back and forth between their machines. Xerox was not able to exploit the technology at the time, because of the high cost and low performance of microelectronics. In the 1960s, Gordon Moore, a founder of the Intel computer chip corporation, propounded what has become known as Moore's Law, the observation that the performance of computer chips was doubling every eighteen or twenty-four months. Alto's technology finally hit the home market when the first Apple Macintosh was sold in 1984, soon followed by Microsoft's Windows operating system.

Before any of the big information technology companies offered personal computers to the public, hobbyists were building their own from kits, notably the Altair first announced in the January 1975 issue of *Popular Electronics* magazine. A technological social movement, drawing on some of the cultural radicalism of the 1960s, quickly spread across America and Western Europe, although in retrospect it is difficult to estimate how much this radicalism contributed

Arenas in Korea host regular competitions between the country's finest video and computer gamers. The events are televised, and the competitors are treated like movie stars.

to the rapid advance of the computer revolution. It is true that Apple was founded in a garage by two friends, and Bill Gates dropped out of college to help his buddies found Microsoft. For a few years after the Apple II computer appeared in 1977, an individual could write a commercially viable software program and start a small company to market it. But the greatest advances after the mid-1980s again required the combination of massive government funding and large corporations.

Internet and the World Wide Web

Internet was born in 1969 as ARPAnet, a research network funded by the Advanced Research Projects Agency of the U.S. government that connected computers at the University of California at Los Angeles, the Stanford Research Institute, the University of California at Santa Barbara, and the University of Utah. In 1972 it was first demonstrated to the public, and in the same year it began carrying email. More and more educational institutions, government agencies, and corporations began using the Internet—and finding new uses for it—until by the end of the 1980s it was an essential tool for research and had begun to demonstrate its value for business and personal applications. For example, in 1978 Roy Trubshaw

and Richard Bartle invented the first online fantasy game or MUD (Multiple-User Dungeon) at Essex University in England, and in 1989 Alan Cox at the University College of Wales released his own version onto the Internet.

In 1990 at the high-energy physics laboratories of the Conseil Européen pour la Recherche Nucléaire (CERN) near Geneva, Switzerland, Tim Berners-Lee developed the first hypertext browser and coined the term World Wide Web. Early in 1993, University of Illinois student Marc Andreessen at the National Center for Supercomputing Applications, funded by the U.S. National Science Foundation, programmed the first version of Mosaic, the easy-to-use browser that would introduce millions of people to the Web. Both the Netscape and Microsoft Internet Explorer browsers were based on Mosaic, and it is estimated that more than 10 percent of the world's population used the Internet in 2002.

The mainframe-timesharing concept of the 1970s has evolved into what is called *client-server architecture*. A server is a dedicated computer, often large, that houses centralized databases (in companies, universities, or government agencies) or connects directly to the Internet. Originally, clients were dumb terminals with little or no computing power of their own, but today they are powerful personal computers connected

to the server and able to access its resources. A very different approach has arisen recently, called *peer-to-peer architecture*—for example, the music-file-sharing programs like Napster that link personal computers over the Web, in which each computer simultaneously functions as both server and client. The *grid computing* concept distributes big computation jobs across many widely distributed computers, or distributes data across many archives, eroding the distinction between individual computers and the Internet.

The Era of Ubiquitous Computing

Computers today are found nearly everywhere, embedded in automobiles and grocery store checkout counters, or packaged as pocket-sized personal digital assistants that allow a user to send email or surf the Web from almost anywhere. They have begun to take over the roles of traditional devices such as telephones and televisions, while other devices have become accessories to computers, notably cameras and music players. Old forms of computing do not die, but expand. Children's toys now have vastly greater computing power than ENIAC, but ENIAC's direct descendents are supercomputers capable of doing dozens of trillions of calculations per second.

Computer science continues to advance, and nanotechnology promises to sustain Moore's Law until perhaps about 2025, halting only after the smallest electronic components have shrunk to the size of a single molecule. Two decades of doubling every eighteen months means improvement by a factor of 8,000. That would imply the computing power of today's desktop computer packaged in a shirt button and costing a dime. What will people do with such power?

In 2003, the Interagency Working Group on Information Technology Research and Development of the U.S. government identified the following "grand challenges" that computing could address in the following decade:

- Knowledge environments for science and engineering

- Clean energy production through improved combustion
- High confidence infrastructure control systems
- Improved patient safety and health quality
- Informed strategic planning for long-term regional climate change
- Nanoscale science and technology: explore and exploit the behavior of ensembles of atoms and molecules
- Predicting pathways and health effects of pollutants
- Real-time detection, assessment, and response to natural or man-made threats
- Safer, more secure, more efficient, higher-capacity, multimodal transportation system
- Anticipate consequences of universal participation in a digital society
- Collaborative intelligence: integrating humans with intelligent technologies
- Generating insights from information at your fingertips;
- Managing knowledge-intensive dynamic systems
- Rapidly acquiring proficiency in natural languages;
- SimUniverse [educational computer simulations]: learning by exploring
- Virtual lifetime tutor for all

Technology— Firearms

Between the eleventh century and the 1830s, firearm technology developed fairly slowly and equally around the globe; the developments that most affected societies occurred after industrialization and were adopted by the military. Today the mass production of personal firearms—ranging from hunting rifles to handguns to paramilitary weaponry—has brought the impact of firearms well beyond the military sphere.

The history of firearms can be divided into two eras: an age of smoothbore weapons (weapons whose barrel has an unrifled bore), up to about 1830, and an age of rapid technological innovation and industrialization after 1830. The first age saw relatively slow technological development and relatively few disparities in the impact of firearms around the globe. The second age, however, created vast disparities in military strength throughout the world and had a much broader impact upon society as a whole.

Invention and Spread of Firearms to 1830

Gunpowder first appeared in China during the Song dynasty (960–1279), probably during the eleventh century, an ironic by-product of a Daoist search for an elixir of immortality. It was used by the Chinese in fireworks and in warfare in the form of bombs launched by catapults, proving especially useful in naval warfare. Historians disagree over whether it then spread to Europe via Silk Roads trade routes or whether Europeans invented gunpowder independently. Either way, once in Europe gunpowder was put to use as the moving force behind projectiles,

and firearms were born. The earliest depiction of a gunpowder weapon in manuscripts dates to the late 1330s.

Gunpowder was used first in cannons. By the fifteenth century handheld firearms had also appeared in the form of muskets and their lighter cousin the arquebus (a portable gun usually fired from a support). Both forms of the technology spread not just through Europe but also to most of the rest of the world over the next century. The Ottomans had better cannons than the Europeans by 1450, specializing in huge siege guns that helped them take Constantinople in 1453 and also fielding a musket-bearing corps of janissary (slave) infantry. The Mughals made effective use of cannons in the early 1500s, as did the Ming Chinese. Muskets made it to Japan in 1542 on a Portuguese ship; Japanese smiths soon manufactured muskets as good as European models, and Japanese generals pioneered effective battlefield use of the weapons. African kingdoms traded for muskets and then fought European armies on equal terms in places such as Morocco and Angola in the sixteenth and seventeenth centuries, and Native Americans made effective use of musketry against Europeans in frontier wars during the seventeenth century.

Characteristics and Impact to 1830

Almost all the cannons and handheld guns in this age shared certain characteristics. They were smoothbore weapons and therefore fairly inaccurate individually (rifled muskets—i.e., weapons with spiral grooves cut into their bores—existed, but they were very slow to load and used only for hunting). Even smoothbores were somewhat cumbersome to reload, so rates of fire

Gunpowder, which appeared in China in the eleventh century, was first used in fireworks and naval warfare. This drawing is one in a collection of 179 Chinese drawings mounted on 79 leaves (pages). New York Public Library.

were low compared to bows—the best eighteenth-century units could manage only two to three shots a minute. To achieve a significant battlefield effect, these slow, inaccurate guns had to be employed en masse, either as cannon batteries or in large units of infantry, though skirmishing was also possible in the right terrain. But guns had advantages. The penetrating power of cannon shot was far superior to traditional torsion or tension artillery (catapults and the like); muskets likewise had great penetrating power, rendering much armor obsolete. Above all, handheld firearms were easy to learn to use: several weeks' practice could turn raw recruits into reasonably effective musketeers, whereas good archery was a skill acquired over decades.

The varied impact firearms had in this age derived from these characteristics. Their penetrating power and ease of use combined to pose a potential threat to mounted elite warriors, who found themselves and

their mounts suddenly more vulnerable. Nevertheless, cavalry forces did not cease to be effective with the advent of firearms, and in fact the most formidable armies of the fifteenth and sixteenth centuries, including the Ottomans, the Manchus, and the Mughals, combined the tactical mobility of steppe cavalry with artillery trains and a corps of infantry musketeers. But firearms meant that steppe cavalry could no longer be an independent threat to sedentary armies, especially when their opponents added fortifications and firepower together. So gunpowder played a role in ending the long role steppe nomads had played in Eurasian warfare, but to characterize the great Asian powers of the age as “Gunpowder Empires,” as some historians do, is to overemphasize the role of cannon in what really were synthetic systems in which steppe-style cavalry was still vital.

The notion of “Gunpowder Empires” also derived from the impact of firearms on fortifications: they supposedly rendered pregnunpowder forts obsolete, thereby facilitating wide conquests (at least until new forms of fortification were devised to counter cannon fire). While such an effect was briefly true for some areas of Europe, in many other places, such as India, fortifications could already withstand gunpowder, so guns had little effect on conquest. And in Europe, a new form of fortification arose in Italy around 1525. From one perspective, the *trace italienne* simply restored the defensive status quo. But some historians see in the new fortifications (or, alternately, in the tactical implications of handheld firearms for infantry battle in the European context) the seeds of a “military revolution.” Briefly, the various versions of this theory see gunpowder necessitating larger armies, either to besiege the new fortifications or to provide mass fire on the battlefield. Larger armies in turn required governments to become more organized in order to pay for them. Better governments and their bigger, better armies then launched Europe into its position of world leadership. The military revolution theory therefore inserts firearms as a causal factor in both the emergence of the modern state and the rise of Europe. The theory has been much debated, and is in its simplest form a vast and technologically

determinist overstatement, at the very least; some historians doubt that there was a military revolution at all in early modern Europe. Certainly no area of the world derived a decisive edge from the use of gunpowder weapons alone before the nineteenth century, simply because the technology was so widely diffused. Whatever edge European arms had by the late eighteenth century was based on organizational techniques, not technology, and was limited in its reach by transport problems.

On the other hand, the combination of firearms, especially cannons, and full-rigged oceangoing ships did create a revolution of sorts at sea, though claims for even this must be qualified by the lack of serious competition from Asian powers (arising largely from different interests, not technological barriers). Still, effective exploitation of the seas lay at the heart of growing European influence in the world by 1800, and the European leader in this sphere, Great Britain, was arguably the first to create a “modern” fiscal-military state and military-industrial complex focused on the navy. By 1800, also, Napoleon and the armies of the French Revolution were bringing to a pinnacle the operational and tactical art of land warfare in the age of smoothbore firearms.

Technological Innovations since 1830

The first great change in the smoothbore equation came in 1830, when rifled muskets that could be reloaded as rapidly as smoothbores appeared, thanks to the invention of a bullet with a hollow base. The ball was smaller than the rifled bore and could be rammed home, but the base expanded when fired, filling the rifling. The spin imparted by rifling increased both accuracy and range, which almost tripled in effective terms. Suddenly, cavalry were driven from any significant battlefield role, and infantry attacks became much more expensive and difficult. Further innovations followed in the course of the nineteenth century. Breech loading allowed infantry to reload lying down and so take greater advantage of cover. Better metal casings allowed bigger, more powerful shells. Smokeless powder allowed further concealment.

The Bren light machine gun was featured on one in a set of fifty cigarette cards (now valued as collectibles similar to baseball cards), called *Britain's Defenses*.

Mechanisms for rapid or multiple shots, including the invention of machine guns, gave two or three men the firepower of an entire Napoleonic brigade. Similar improvements affected larger firearms. Land artillery and naval guns saw the introduction of aerodynamic exploding shells, steel barrels, and armor-piercing points. Perhaps more important than any particular improvement was the introduction of interchangeable parts in gun manufacturing, which allowed the industrialization of weapons making. Mass production meant that armies could be supplied with new weapons more quickly, which encouraged more rapid

technological change and soon led to the widespread commercialization of firearms beyond military uses. The twentieth century saw firearms mounted on motorized vehicles and carried into the air on planes, and by the end of the century munitions were becoming “smart” as computer technology began to change firearms significantly.

Impact since 1830

These changes in firearms technology vastly increased the impact of firearms in the world. In Europe and the United States, where the new technologies were developed, firepower led to a series of tactical revolutions first visible in the trench warfare around Petersburg, Virginia, in 1864. At first, almost all the changes favored the defense in battle. Attempts to break the defensive power of artillery, machine guns and rifles led to the development of mechanization for increased mobility, including mobilization of armies via railroads and then the use of vehicles with internal combustion engines on land and in the air for

troop transport and as fighting vehicles. Firepower also called forth the use of armoring, first on ships and later on tanks and other land vehicles. Greater and greater firepower carried by more mobile armies, air forces, and navies inevitably spread the impact of war far beyond the traditional frontline, increasingly blurring the distinction between combatant and noncombatant.

Very much unlike the firearms technology of the smoothbore age, firepower in the industrial age created (and continues to create) vast disparities in military capabilities around the globe. Small armies of Europeans armed with rifles and machine guns could by 1870 face down many thousands of indigenous warriors. Firearms, in other words, became central to creating the imperialism of the nineteenth century as well as to its maintenance well into the twentieth. But the widespread availability of firearms embodied in a worldwide arms trade, a trade later given impetus by ideological conflicts such as the Cold War, also helped bring down colonial empires in the second half of the twentieth century. Following in the footsteps

Lo! Men have become the tools of their tools. • Henry David Thoreau (1817–1862)

of Mao Zedong and the Chinese Communist Army, the leaders of anti-colonial rebellions (and later of antigovernment insurgencies of all stripes) made use of firepower through guerilla tactics to cause major problems for conventional armies. The firepower of such groups also increased their ability to damage civilian populations, a problem often exacerbated by ethnic or nationalist tensions in civil wars. Arms-control agreements focused on weapons of mass destruction have done little to stem the worldwide flow of personal firearms to any group that wants them.

In addition, the industrialization of weapons manufacturing and the widespread availability of personal firearms—ranging from hunting rifles to handguns to paramilitary weaponry—that resulted from mass production carried the impact of firearms well beyond the military sphere. Given the potential for damage that modern firearms give to individuals and small groups, most governments that were capable of doing so moved to restrict the availability of firearms to the civilian population, an extension of previous policies aimed at disarming the general populace in favor of the central authority, thereby maintaining a monopoly on the legitimate use of force. But weak or faction-ridden governments proved incapable of enforcing such policies, with bloody results that often showed up in periods of civil war or insurgency. And the policies of the United States government (inspired by some readings of the Second Amendment) have traditionally imposed fairly minimal restrictions on gun ownership and use, resulting in high levels of gun-related violence and murder rates significantly higher than those in comparable industrialized countries with more restrictive policies. Meanwhile, the image of firepower has entered mainstream popular culture around the world through films and computer games, the “shoot-‘em-up” being a major genre of each medium. The impact of firearms in world history, whether military, political, social or cultural, therefore

stands as a case study of the growing complexity and interconnectedness of technology and human social relations visible in all areas of world history.

Technology— Overview

Over the course of our evolution we humans have developed tools and skills—technologies—using our most powerful resource, the brain. To understand history, we must know who possessed what technologies and how they used them. The history of technology is the history of power over nature and over people.

Human beings cannot fly, or fight with their teeth and claws, or run, swim, or climb as handily as other animals. Instead, using our brains, we have devised tools and skills that have given us power over the natural world and permitted us to thrive almost everywhere on the planet. These tools and skills—in a word, technology—have also given some people power over others.

Before and During the Advent of Agriculture

Humans and their tools evolved symbiotically over millions of years. The hominid *Australopithecines* who lived in Africa from 4 to 2.5 million years ago used river cobbles as crude choppers to smash the bones of dead animals. Their descendents, members of the species *Homo erectus*, made hand axes by breaking flakes off both sides of a stone; they also learned how to control fire. With these tools, some hominids hunted big game while others gathered plants and insects. The size of their brains increased in tandem with their use of tools, while their teeth and jaws grew smaller.

The species *Homo sapiens*, humans like ourselves, appeared more than 150,000 years ago. They made a multitude of specialized tools, such as spear points, scrapers, and blades. Beginning 70,000 years ago, humans made clothing, houses, and oil lamps, as well as cave paintings, musical instruments, and decorative jewelry. With their advanced hunting and gathering equipment and skills, they migrated to previously uninhabited areas, such as Siberia and the Americas. They had boats of some sort, with which they crossed miles of open sea to reach New Guinea and Australia. They moved frequently in search of game and plant foods. Some 30,000 years ago, humans learned to sew clothing, using bone needles and sinew as thread, which allowed them to survive in formerly uninhabitable areas of the world like Siberia. Then, after 10,000 BCE, hunters began using bows and arrows to kill elusive and fast-moving game like deer and gazelles.

Permanent settlements coincide with the development of agriculture. Starting some 12,000 years ago, people in the Middle East began to harvest wild wheat and barley, and to help these plants grow by sowing seeds and clearing away weeds. To chop down trees, they made smooth-sided stone axes. By storing grains from

This Acheulean handaxe (one type of stone tool made by prehistoric hominids) was found near Kibish, Ethiopia, where human bones believed to be 195,000 years old were also discovered.

Arrow points (top) were reworked and refined through experimentation, often from dart points (bottom). This photo shows the difference between the two types in size and neck/stem width. University of Missouri.

one harvest to the next, they were able to stay in one place and build permanent houses; the first known settlement was Jericho, founded c. 7350 BCE. They also domesticated animals: first dogs, then sheep and goats, then pigs, donkeys, and cattle. Agriculture developed in China and Southeast Asia in the ninth millennium BCE, in Europe from the seventh millennium, in West Africa from the fourth, and in Mexico from the second millennium on. In the Americas, the process started later and took longer because there were fewer wild plants and animals that could be domesticated: corn, beans, and squash were the primary domesticated plants, and dogs, turkeys, guinea pigs, and llamas the primary domesticated animals. Other tools and skills that made possible agriculture and animal husbandry included digging sticks and hoes to prepare the ground, sickles to harvest grains, baskets and bins to hold crops, and fences to keep animals.

The shift to agriculture and animal husbandry took two thousand years, during which time people continued to hunt and gather wild foods. By growing and

raising food, far more people could survive in a given area than was possible if they relied on the bounty of nature. Once their population grew, however, they could no longer return to their old lifestyle.

Hydraulic Civilizations (3500–1500 BCE)

As agriculture spread, people who lived on the banks of rivers, especially in hot dry regions, found that they could obtain phenomenal yields by watering their crops. To irrigate away from the riverbanks meant digging canals and constructing dikes. In the lower valley of the Tigris and Euphrates rivers in Mesopotamia (now Iraq) the Sumerians (who arrived in the region between 4000 and 3500 BCE) organized large numbers of workers to carry out these public works projects. They used well-sweeps (a bucket at the end of a counterbalanced pole) to lift water from the canals to their fields. By the mid-fourth millennium BCE, the resulting food surpluses allowed their leaders to build cities, create governments and laws, and employ artisans, bureaucrats, soldiers, and merchants. In Mesopotamia, cities built ziggurats, multistory temples made of sun-dried bricks.

The same social revolution occurred in Egypt in the late fourth millennium, for the same reasons. Every year, the Nile River flooded the valley. To retain the water, farmers built dikes to enclose basins; once the soil was thoroughly soaked, the water was released to the next basin downstream. All of this required massive amounts of labor. During the off-season, farmers were recruited to build pyramids and temples.

Irrigation and water control were the key technologies of several other early civilizations. In northern China, civilization grew out of the need to protect the land from the dangerous floods of the Huang (Yellow) River. In the Valley of Mexico (central Mexico), farmers built raised fields called *chinampas* in shallows lakes by digging canals and heaping the rich mud on their plots. On the coastal plains of Peru, among the driest environments on Earth, farmers used the rivers that came down off the Andes to irrigate their fields. The people of Peru built cities with great walls of massive stones that fit together perfectly.

It is questionable if all the mechanical inventions yet made have lightened the day's toil of any human being. • **John Stuart Mill (1806–1873)**

Early civilizations also developed other technologies. Women spun thread and wove cloth, some of exquisite beauty, out of flax in Egypt, wool in Mesopotamia and Peru, silk in China, and cotton in India and the Americas. Potters made pots for storage and cooking. Smiths learned to smelt metals from ores, first copper and later bronze, an alloy of copper and arsenic or tin. Wheeled carts were first used in Anatolia (now Turkey) and Mesopotamia in the fourth millennium, and spread from there to the rest of Eurasia.

Iron and Horses (1500 BCE–1500 CE)

The elites of first civilizations were very conservative, yet they could not prevent technological changes and the disruptions they caused. Among the many innovations that spread throughout the Eastern Hemisphere in the second millennium BCE, we can single out the two that had momentous consequences: the utilization of iron and the domestication of horses.

Iron, first smelted in Anatolia around 1500 BCE, required much more labor and fuel to make than bronze, but unlike copper and tin, its ores were found almost everywhere. Once blacksmiths learned to temper iron by repeated heating and quenching in water, it became hard enough to cut bronze. The low cost of iron made it possible to produce axes and saws for farmers and carpenters and knives and pots for household use.

Iron spread to the Middle East around 1000 BCE, and from there to Africa and India. Iron tools gave a tremendous advantage to those peoples who used them at the expense of nature and of people with less-developed technologies. Bantu-speaking people from the Nigeria-Cameroon region cleared wooded areas of central and southern Africa for agriculture and gradually pushed earlier inhabitants such as the Batwa (known by the pejorative term *Pygmies*), and San into forests and deserts not suitable for agriculture. In India, people with axes spread into the Ganges valley and the Deccan Plateau, turning forests into farmlands.

The Chinese created the most advanced iron industry.

Not only did they make iron by hammering and tempering, like the peoples of Eurasia and Africa, they also invented bellows pumped by waterwheels that heated the furnace to the point at which the iron melted and could be poured into molds. As the deforestation of central and southern China proceeded, iron makers learned to heat their furnaces with coal. By the late first millennium CE, China was mass-producing iron tools, weapons, and household objects such as pots, pans, knives, and bells.

In the Middle East, meanwhile, blacksmiths learned to make “damascene” blades (after Damascus in Syria) by repeatedly heating a strip of iron in burning charcoal, hammering it thin and folding it over, until the iron turned to steel, becoming hard, sharp, and flexible. Such a process was extremely time-consuming and was used only for very costly swords.

Horses were first tamed in the third millennium BCE, but were of limited use until carpenters began building chariots with spoked wheels, pulled by two horses and carrying two men, one to drive the horses and the other armed with a bow and arrows. Charioteers from the grasslands to the north invaded the agrarian civilizations of the Middle East, India, and China, causing great havoc between 1700 and 1300 BCE. Chariots in turn were made obsolete around 1200 BCE when nomadic herdsman learned how to shoot arrows while riding a horse. After about 1500 BCE, the agrarian states added cavalry and iron weapons to their infantry armies and established large empires of conquest. The Assyrians, Persians, and Romans in turn dominated Southwest Asia and the Mediterranean, while the Qin and Han dynasties controlled China. These empires, extending over thousands of miles, were held

Harvester's sickle from the Sumerian culture, Iraq, 3000 BCE, made from baked clay.

together by efficient road networks and postal services. The Romans were especially gifted at civil engineering; many of their roads, buildings, and aqueducts are still standing. However, nomadic herdsman from the

Developments in agriculture led to innovations like the iron plow; here a farmer tills a rice paddy. From the *Illustrated Guide of Tilling and Weaving: Rural Life in China*, pictures by Bingzhen Zhao (1680–1720).

grasslands of Asia continued to increase in numbers and in military might, and periodically attacked the agrarian civilizations. For two thousand years, the history of Eurasia consisted in large part of the struggle between agrarian empires and nomadic herds-men. For centuries after they were domesticated, horses could not be used in agriculture because the throat-and-girth harness caused them to choke and rear up if they had to pull a heavy load. The horse collar, which placed the load on their shoulders rather than their throats, first appeared in China in the third century BCE and reached Europe between the ninth and the eleventh centuries CE.

Advances in Agriculture (1500 BCE–1500 CE)

Agriculture was also transformed during this period. As Han Chinese moved from northern China into the tropical Yangzi (Chang) River valley and the south, they perfected the art of water management. Rice grows best in warm shallow ponds, but requires very careful terracing, plowing, planting, weeding,

water control, and harvesting, most of which had to be done by human labor. In addition to rice, Chinese farmers also grew tea bushes and mulberry trees, whose leaves fed the silkworms for the silk industry. In return for more intensive labor inputs, the land produced ever more abundant yields per acre. As its population grew, China became the wealthiest and technologically most advanced civilization in the world, producing such innovations as paper, printing, paper money, and (later) the compass, oceangoing ships, and gunpowder.

A different kind of agricultural and technological revolution occurred in the Middle East from the seventh to the fifteenth centuries. The Arabs, a desert people, had domesticated the camel for use in regions too dry for horses. In the seventh century, they conquered the Middle East and North Africa. With a long tradition of trade, they welcomed and protected merchants and sailors. They rebuilt the irrigation works of Egypt and Mesopotamia and introduced several useful devices such as the *saqiya* (a chain of buckets) and the *qanat*, or underground tunnel, to carry water over long distances. They also introduced citrus fruits from China and sugar and cotton from India to the Mediterranean world.

European agriculture lagged far behind agriculture in China and the Middle East, especially after the collapse of the Roman Empire after the fifth century. Yet Europeans created several ingenious innovations that allowed them to populate the western and northern portions of the continent, which the Romans had found uninhabitable. One was the three-field rotation system, whereby fields lay fallow one year out of three, instead of every other year as in earlier times, resulting in a 50 percent increase in productivity. Another was the iron horseshoe, which prevented horses' hooves from wearing out in wet weather. A third was the horse collar, which allowed a horse to pull much heavier loads than the throat strap used by the Romans. Europeans were also quick to adopt water wheels and windmills as sources of energy to grind grain, saw lumber, crush ores, and accomplish other tasks. While the yields per hectare in Europe in this period could not compare with those in China or

the Middle East, the result of these innovations was to make the yields per person the highest in the world.

Technologies of Global Interaction

Ocean-going ships carried not only men and trade goods, but also animals and plants from one place to another. Domesticated plants and animals have been essential technologies since the Neolithic, requiring knowledge and skills to grow or breed them and to transform them into foods and fibers. From the beginning of agriculture, plants and animals had been transferred within the Eastern Hemisphere and also, with more difficulty, within the Americas. The voyages of the fifteenth and sixteenth centuries allowed transfers between the Old World and the New. The Europeans brought with them wheat, rice, sugar, and cotton, along with many fruits, vegetables, and trees. From the Americas they returned with corn, potatoes, and tobacco, among others. The Portuguese transferred cassava (manioc) from Brazil to Africa and Indonesia.

Europeans also brought their animals with them wherever they went. Pigs and cattle ran wild in the Americas. Horses were used by Europeans and by the Plains Indians of North America. The New World had almost no animals to offer in exchange, however. Introduced crops and animals increased the food supply and contributed to the rise in population around the world. In the process, they accelerated the transformation of local environments and the destruction of native plants and animals. In the fifteenth century, improvements in ships and navigation led to the diffusion of other technologies around the globe. Let us consider two important technologies with global repercussions: navigation and gunpowder.

Navigation

People had long navigated on rivers and lakes and along seacoasts. Humans reached New Guinea and Australia tens of thousands of years ago. Malay people from Southeast Asia migrated to Indonesia and reached Micronesia and New Caledonia by 2000 BCE.

Columbus's *Santa Maria*, *Nina*, and *Pinta* are perhaps the most famous examples of the popular caravel ship design, used by Portugal and then Spain for exploration and trade. New York Public Library.

Others crossed the Indian Ocean to Madagascar. They learned to navigate by observing the stars, the sun, and the moon and by feeling the ocean swells. Gradually, they ventured out into the Pacific Ocean in dugout canoes equipped with outriggers and triangular “crab-claw” sails, finally reaching Hawaii and New Zealand. The peoples living along the Mediterranean Sea, by contrast, did not develop oceangoing vessels. Their cargo ships were broad-beamed with a square sail and could sail only in good weather and preferably with the wind. Their warships were propelled by oarsmen and were designed to ram and board enemy ships. Neither was suited to travel on the Atlantic.

The Indian Ocean lends itself to regular navigation because of the monsoons that blow toward Asia in the late summer and autumn and away from that continent in the winter and spring. In the early centuries of the common era, Arabs, Persians, and Indians built dhows, small sailing ships made of teak planks sewn together with coconut fibers with a lateen, or triangular sail, that could sail at an angle to the wind. The prosperity of the Indian Ocean trade was the envy of both Chinese and Europeans.

Beginning in the Song dynasty (960–1279), the Chinese developed a kind of ship called a junk, with a flat bottom, bamboo sails, and a sternpost rudder. Captains were equipped with magnetic compasses and charts of the waters they sailed in. Between 1405 and 1433, the Chinese government sent seven expeditions to the Indian Ocean. The first included 317 ships, some of which were 120 meters long and 48 meters wide. With the largest ships and the most

A freight train crossing a fill. New York Central Railroad.

powerful fleet in the world, the Chinese could have explored all the oceans of the world. But when warfare with nomadic tribes from Mongolia absorbed the government's resources and attention, the government ended the expeditions and prohibited ocean navigation.

Meanwhile, Europeans were becoming more adept at navigation. By combining the best features of the Mediterranean oared galleys and the round-hulled sailing ships of the North Sea, the Portuguese created a ship called a caravel that had both square and lateen sails and a sternpost rudder, and that could be sailed in any wind with a small crew. During the fifteenth century, they figured out the wind patterns of the Atlantic. With such ships and knowledge Christopher Columbus (1451–1506) crossed the Atlantic in 1492, and Vasco da Gama (1460–1524) reached India six years later.

Gunpowder

Gunpowder was first used in China in the thirteenth century for flame throwers and fireworks. In the fourteenth century, Europeans and Turks began casting large cannon that could hurl iron cannonballs and destroy the walls of fortified cities. Artillery gave a great advantage to centralized states like those of the Ottoman Turks, the Mughals in India, and the czars of Russia. Western Europeans were the first to build smaller naval cannon and ships strong enough to

withstand the recoil of guns in battle, and with these they quickly dominated the Indian Ocean and the waters off East and Southeast Asia.

The Industrial Age (1750–1950)

Beginning in the mid-eighteenth century, a new set of technologies, which we call industrial, began to transform the world. Industrialization had five defining characteristics: an increased division of labor; the mechanization of production and transportation; energy from fossil fuels; mass production of goods and services; and the diffusion of practical knowledge. Each of these had been tried in various places before—for example, books were mass produced from the sixteenth century on—but it is the combination of all five that defined true industrialization.

Industrialization began with the British cotton textile industry, which used machines powered by flowing streams to produce cloth in large quantities at low cost. At the same time, abundant coal was used to produce cheap iron. The most spectacular invention of the eighteenth century, and the one that distinguished the British industrial revolution from all previous periods of rapid change, was the steam engine, improved by the condenser James Watt (1736–1819) patented in 1769. By the mid-nineteenth century, steam engines were used to pump water, turn machines, and power locomotives and ships.

The new industrial technologies spread to other countries, but very unevenly. Western Europe and northeastern North America soon followed Britain's lead, but the rest of Europe and Russia lagged behind until the late nineteenth century. India and Latin America imported machines and technicians, but not the engineering culture that would have lessened their dependence on the industrial nations. Of all the non-Western nations, only Japan began industrializing before 1900.

Meanwhile, a second wave of industrial technologies appeared in the late nineteenth and early twentieth centuries, mainly from Germany and the United States. Inventors found ways of mass-producing steel—formerly a rare and costly metal—at a cost so

low that it could be used to build bridges and buildings and even thrown away after use. The German chemical industry, founded to produce synthetic dyestuffs, expanded into fertilizers, explosives, and numerous other products. Electricity from batteries has been used since the 1830s to transmit messages by telegraph, but after 1860 generators and dynamos produced powerful currents that could be used for many other purposes. In 1878, Thomas Edison (1847–1931) invented not only the incandescent light bulb, but also the generating stations and distribution networks that made electricity useful for lighting and later for electric motors, streetcars, and other applications. In 1895, Guglielmo Marconi (1874–1937) created the first wireless telegraph, the ancestor of radio.

The beginning of the twentieth century saw the introduction of two other technologies that revolutionized life in the industrial countries and, later, in the rest of the world. In 1886 Karl Benz (1844–1929) and Gottlieb Daimler (1834–1900) put an internal combustion engine on a “horseless carriage.” In 1913 Henry Ford (1863–1947) began building his Model T on an assembly line, making cars so inexpensive that even workers could afford them. By the 1920s, automobiles were common in the United States. After the mid-century, they became common in Europe as well.

The other revolutionary invention was the airplane. The brothers Wilbur (1867–1912) and Orville (1871–1948) Wright were the first to fly in 1903. They were soon followed by others on both sides of the Atlantic. From the 1950s onward, flying became a common means of transportation around the world.

In peacetime, mass production meant mass consumption of cotton clothes, railroad transportation, automobiles, and other consumer items. But industrial production also made possible mass destruction in two widespread and murderous World Wars and in the annihilation of entire populations. Yet even after the most destructive wars in history, the nations that

Thomas Edison’s first light bulb “lit up” publicly at a demonstration in Menlo Park, 1879.

had suffered the heaviest damage—Russia, Germany, and Japan—were able to rebuild remarkably quickly. Industrialization spread more slowly to South Asia, the Middle East, and Latin America, and has not yet begun in earnest in most of Africa. The industrial world is still an exclusive club.

The Postindustrial World

Postindustrial does not mean that industry is disappearing; on the contrary, there is more industry producing more products than ever before. Yet we are clearly in the midst of another technological revolution, as dramatic—but much faster—than the agricultural and industrial revolutions that preceded it.

The new revolution involves many technologies that can trace their origins to World War II. In that war, governments understood that their hope of victory rested on developing new weapons and other military technologies. Such research programs were extremely costly, yet invention

The first Model T Ford, 1908, was so inexpensive even factory workers could afford to buy one.
New York Public Library.

The Wright Brothers' 1903 airplane. United States National Museum, Washington.

proceeded at an accelerated pace that would not have been possible if governments had relied on private enterprise. This realization led governments to continue funding research long after the war was over.

War-Related Technologies

The most dramatic invention of the war was the atom bomb, built by the United States between 1942 and 1945. After the war, the Soviet Union also built atom bombs, which were followed in the 1950s by the far more powerful hydrogen bomb. Nuclear energy was not limited to bombs. Nuclear reactors were harnessed to produce electricity and to power submarines and other ships.

In 1957, the Soviet Union launched the first artificial satellite, *Sputnik*. The rocket that hoisted it into orbit was based on the V-2 missile built by Germany during the war. *Sputnik* was the precursor of thousands of satellites put into space for espionage and surveillance, television broadcasting, and telecommunications. The most spectacular event of the space age was the Moon landing of 1969, proof of humankind's growing power over the natural world.

Electronics

Future historians will no doubt consider the new electronic technologies even more revolutionary than nuclear and rocket technology. Television, still experimental before the war, became a consumer item in the 1950s in the United States and in the 1960s in

Europe and Japan. Radar, developed during the war for military purposes, later served civilian aviation, navigation, and law enforcement. Computers, also invented during the war, became important business tools with IBM's System 360 in 1964 used in the banking, insurance, and retail industries, among others. Apple made the first popular personal computers in the late 1970s, but was soon overshadowed by IBM and a host of smaller companies that purchased operating systems and programs from the giant of the software industry, Microsoft. In the mid-1980s, the Internet began linking computer networks around the world. The World Wide Web, introduced in 1991, made it possible to send images as well as text, and made the Internet so user-friendly that companies soon used it to advertise and sell their products. Most computer hardware and software originated in the United States, but the manufacture and marketing of consumer electronics was dominated by Japanese companies.

Biotechnology

Biotechnology is another area that has seen rapid technological development. In 1953, James Crick and Francis Watson discovered DNA, the substance that encodes all the information needed to create living beings. Their findings promised advances in medicine, agriculture, and other fields. In the 1970s, agronomists created more productive hybrids of rice, wheat, corn, and other crops: the Green Revolution. Since the mid-1990s, genetically modified organisms have confronted nations and their farmers and consumers

The mushroom cloud resulting from the nuclear bomb detonated during a test at the Bikini lagoon, 25 July 1946.

with a controversial trade-off between present benefits and future risks.

Technology and the Future

The power of humans over nature has increased at an accelerating rate. Now humans are capable of extraordinary achievements, but also extraordinary damage to one another and to the planet. Advances in computers and communications will soon offer those who can afford them instant access to every text, film, or piece of music, and will enable powerful governments to track every vehicle and perhaps every person on Earth. Nuclear power has the potential to replace fossil fuels, but its exploitation also makes possible the creation of dangerous weapons, which may fall into the hands of desperate individuals. Biotechnology promises better health but also the manipulation of all forms of life in ways never imagined; cloning in particular is a headline-grabbing new technology fraught with difficult social and moral implications. These technologies and others not yet imagined are double-edged swords for those who possess them. Meanwhile, those who have no access to modern technologies—half or more of humankind—are no better off than they were a thousand years ago.

Telegraph and Telephone

The telegraph and the telephone are communications media that transmit messages by coded signals. The telegraph conveys written messages and the telephone transmits voice. Both media developed rapidly in the nineteenth and twentieth centuries and form the foundation of the electronics revolution of our time.

The technology to send messages by means of coded signals developed with great speed in the nineteenth and twentieth centuries; the telegraph and the telephone marked the advent of the electronic communication capabilities we take for granted today. But well before the eighteenth century, attempts were made in many parts of the world to use visual telegraphy—messages sent over long distances using such media as smoke signals, fires, and mirrors, usually in one direction only—to warn of approaching enemies. During the French Revolution, Claude Chappe (1763–1805) devised a system of articulated beams and arms that could be moved to indicate numbers, letters, or phrases in a code book. These devices were placed on towers situated approximately 5 to 10 kilometers apart. After the success of their first line in 1794, the French government built a network across France and into neighboring countries. Similar systems were built in other countries, but only over short distances. At the same time, officers of Britain's Royal Navy developed a new system of flags and code books that allowed two-way communication between ships. These were the first systems that could freely send messages over long distances in either direction. Thus in 1794, the French government in Paris received news of the victory of its army at Condé within minutes of the event, and at Trafalgar in 1805,

Admiral Nelson was able to obtain information and control his ships during the course of the battle.

Early Electric Telegraphy

In the late eighteenth and early nineteenth centuries, many inventors tried to send messages over wires by electricity. The electric battery, invented in 1800, and the electromagnet, developed in the 1830s, made such a project possible. In 1837 two Englishmen, William Cooke (1806–1879) and Charles Wheatstone (1802–1875), patented a system that used six wires and five needles (later reduced to two) to point at letters and numbers on a board. Their system was installed on railroad lines in Britain. That same year the American Samuel F. B. Morse (1791–1872) patented a code of dots and dashes that could send signals over a single wire. He opened the first electric telegraph line in the United States, from Washington to Baltimore, in 1844.

Electric telegraphs were an instant success in Europe and North America. By 1848, all the cities of North America east of the Mississippi were connected by telegraph wires. The Western Union Company, founded in 1856, quickly dominated the North American telegraph industry. By 1861 its lines connected San Francisco with the East Coast, and it was planning a land line to Europe via Alaska and Siberia when the Atlantic cable made such a line unnecessary. European governments either started building telegraph networks or bought out the first companies. To connect their various national networks, several European countries, later joined by others, formed the International Telegraph Union in 1865.

Invention is the mother of necessity. • **Thorstein Veblen (1857–1929)**

Telegraphs were so indispensable to the safe and efficient operation of trains that railway companies gave free right-of-way to telegraph lines in exchange for free service. Telegraphs were valuable business tools, conveying commodity and stock prices and other time-sensitive information. They were also used by newspapers, which competed by presenting the latest dispatches bought from the Associated Press (founded in 1848), Reuters (1851), and other news agencies. Governments also made use of the telegraph, especially in times of war and other emergencies.

Outside of Europe and North America, progress was slow. Colonies of the European powers, such as India and Algeria, got their first telegraph lines in the 1850s, as did several Latin American countries and the Ottoman Empire. In China, Africa, and much of the Middle East, governments were reluctant to admit this new form of Western intrusion. Environmental conditions and popular resistance often made it difficult to install and maintain telegraph lines.

Later Electric Telegraphy

Telegraphy continued to advance technologically until the mid-twentieth century. Beginning with a line across the English Channel in 1851, entrepreneurs laid insulated cables across seas and oceans. After several spectacular failures, the technology was finally perfected in 1865 and 1866 with the laying of the first successful transatlantic cables. That success encouraged entrepreneurs to lay cables in other parts of the world: from Europe to India in 1870, to Australia, China, and Latin America in the early 1870s, and around Africa in the 1880s. By the end of the century, all the continents and major islands were connected in

a global network dominated by Western Union and the Commercial Cable Company in the North Atlantic and elsewhere by a British firm, the Eastern and Associated Telegraph Companies. The global submarine cable network played a major role in the growth of the world economy and international trade before World War I, during the first age of globalization. That network was also strategically valuable, and gave Britain, France, and the United States a significant advantage over Germany in World War I.

Other advances in telegraph technology improved transmission speeds and reduced labor costs. Thus multiplexing—sending several messages simultaneously over the same wire—was introduced in the 1870s and, starting in the 1920s, automatic teletypewriters and vacuum tube repeaters replaced the manual typing and retransmitting of messages. Facsimile transmissions (faxes) began in the 1930s. By then, however, wired telegraphy had fallen far behind two radically different technologies: telephony and radio.

Telephony

In 1876, Alexander Graham Bell (1847–1922) patented a method of transforming sound into electrical impulses and vice versa, thereby making it possible to transmit the human voice over a wire. His invention was the foundation of an industry that now connects people throughout the world.

At first, telephone networks were mainly local or, at best, regional, for transmission quality deteriorated with distance. Service was expensive, as calls had to be switched by operators

The Chappe semaphore telegraph, invented by Claude Chappe in 1792, was used to relay signals over long distances.

Ships attempt to lay a cable across the Atlantic in 1858. Long-term success came in 1866, when a cable successfully connected Ireland and Newfoundland. From *The Atlantic Cable*, by Bern Dibner, 1959. Smithsonian Institution Libraries.

in telephone exchanges. Beginning in the 1890s, rotary dials and automatic switches permitted a great expansion of service without additional labor. In the United States and Canada, many independent companies competed with the giant AT&T (incorporated in 1885), especially in rural areas. In Europe, the government provided telephone service, usually through the postal and telegraph administration. Outside of Europe and North America, telephones were very rare before World War II, usually limited to government offices and major businesses.

In 1915 AT&T installed vacuum tube repeaters on its longer lines, making it possible to connect New York and San Francisco. A dozen years later, it became possible, though it was extremely expensive, to telephone overseas or to ships at sea.

By the mid-twentieth century, the telephone industry, like the telegraph industry before it, had become mature and technologically conservative. In the United States, local telephone service reached all businesses and most families by the 1950s, but long-distance service was still too costly for the majority of users. In Europe and Latin America, the cost of telephone service was out of reach of the working class. Elsewhere, telephone service was a business tool and a luxury for the urban rich.

Then came a series of innovations that revolutionized the industry and its social effects. The first transatlantic telephone cable, laid in 1956, could carry a dozen calls at once; it was soon duplicated

and extended to other oceans. Starting in the 1960s, satellites and inexpensive transmission stations made global telephony cheap and available worldwide by multiplying the number of telephone conversations

Bell, in New York, calls Chicago in 1892. Gilbert H. Grosvenor Collection, Prints and Photographs Division, Library of Congress.

that could be sent at the same time. On land, microwave towers dramatically lowered the cost of long-distance communications. Fiber-optic cables, introduced in the 1980s, could carry hundreds of thousands of simultaneous telephone conversations. Long-distance calls, both on land and across oceans, were suddenly as cheap as local calls. From 1960 to 1990, for example, the cost of a call from New York to London fell from thirty U.S. dollars to ten cents a minute.

Even as telephony was changing global communications, another series of technological innovations was transforming telephones at the local level. With the computerization of the network, telephones could perform new functions that had not been possible before. Push-button dialing, call waiting, caller identification, and voice mail were among the innovations. It also became possible to use telephones as data communication machines: one could key in numbers to access bank accounts or communicate with programmed answering

machines. The telephone network was also used to carry data between computers, via modems. As with all innovations in electronics, in the advanced industrial countries the initial cost of the new telephony was high but fell rapidly; for their inhabitants, the world soon formed one giant and easily accessible network. Most of the world, however, was left far behind. Today, for example, there are more telephone lines in Manhattan than in all of Africa, and most of the people of India and China have never used a telephone.

Radio Telegraphy and Telephony

The technology of radio began very differently from that of wired telegraphy and telephony, but wireless and wired technologies soon interacted with each other and are now almost indistinguishable. Though there had been scientific experiments before, it was a young Irish-Italian, Guglielmo Marconi (1874–1937), who in

Alexander Graham Bell's telephone.

Guglielmo Marconi was the first to use electromagnetic waves as a means of communication.

1895 was the first to use electromagnetic waves as a means of communication. By 1898 he was able to send messages in code over 40 kilometers, and in 1901 he transmitted the letter “S” across the Atlantic. He quickly established a company to communicate with ships at sea and to compete with the cable companies in transcontinental communications.

For the first decade, transmitters used sparks to create radio waves, but soon others invented devices that could transmit not only dots and dashes, but also voice and music. The most important of these was the triode, or vacuum tube, patented by the American Lee De Forest (1873–1961) in 1907. Starting in 1913, it was used in long-distance telephony, then in radio equipment during World War I.

Until the mid-1920s, long-distance radio telegraphy used long waves that required enormous energy-hungry transmitters. Then Marconi and other researchers found that short waves (200 meters or less, or frequencies of more than 1500 kilohertz—more than 1.5 million wave cycles per second) could be produced by inexpensive small transmitters, yet be heard around the world. While the cables and big long-wave transmitters almost shut down, short-wave communication now came within reach of any ship, island, or remote mining camp. In World War II,

short-wave radios were used by both sides to communicate with airplanes, warships and submarines, tanks, and even spies.

Library of Congress.

At the basic and advanced flying school for Air Corps cadets, Tuskegee, Alabama, Captain Roy F. Morse teaches the cadets how to send and receive code. January 1942. U.S. Government.

Microwave radio (with wavelengths measured in centimeters and frequencies of more than 1,000 megahertz—more than a billion cycles per second) found application not only in radar, but also, from the 1950s, as an alternative to copper cables in telephone networks. As mentioned above, microwave radio transmissions, like fiber-optic cables, dramatically reduced the cost of telephone calls.

In the 1990s the combination of computers and microwaves revolutionized the telephone industry yet again. The invention of cell (or mobile) phones made it possible for people to talk to one another or to send brief text messages while walking or driving. As the cost of cell phone service came down to a level comparable to that of wired telephone service, cell phones became among the most popular consumer items in Europe, North America, and Japan.

The Future of Telecommunications

Technological revolutions in telecommunications, especially from the mid 1980s onward, have caused turmoil in the industry. Former monopolies such as AT&T in the United States and Canada and the postal, telegraph, and telephone administrations (or

PTTs) in other countries suddenly found themselves seriously threatened, for the first time, by upstart rivals. Money poured into the industry, leading to a stock-market bubble and a serious over-supply of bandwidth and communications channels, followed in 2000 by a recession and many bankruptcies. Expansions and contractions are, however, a normal aspect of business expansion in a free-market economy, one that will benefit consumers in the long run.

Developing countries, meanwhile, are finding it difficult to keep up. While the unit cost of telephone calls are low, the initial investment is enormous, and the technical expertise required to install and maintain computer networks and cell-phone systems is beyond the reach of all but a handful of developing countries. The ones with large populations and economies, like China, India, and Brazil, are keeping up by providing advanced services to certain favored regions and social classes; others are falling behind. Thus, the telecommunications revolution is putting many developing nations at a more serious disadvantage than they were already.

If the recent past is a guide, we can expect as many surprises in the twenty-first century as in the twentieth. Telephone and Internet service will continue

Radar reveals violent thunderstorm activity and heavy rain to the southwest of Spring Lake Army Air Forces Headquarters, August 1945. National Oceanic and Atmospheric Administration.

to penetrate, however unevenly, into the remotest areas of the world; someday, perhaps, everyone will be connected to everyone else. The quality of telecommunications is also likely to change, perhaps with the introduction of video on demand anywhere at any time. Those technological marvels, however, are no more likely than the technological revolutions of the past to bring about world peace or alleviate poverty.

Television

Since television became publicly available in the 1930s as a medium for transmitting and receiving moving images and sounds, its role in the world has become so vast that treating it as a unitary phenomenon with a single line of history is nearly impossible. The technical origins of television can be traced to different parts of the world; its cultural impact can now be felt in every sector of life—for viewers and nonviewers alike.

Television (or TV) is an electronic transmission system that sends and receives visual images and sounds from a source to multiple receivers. The word *television* also refers to the set that receives and interprets the electronic signals of images and sounds. But television is so much more than the technology: television is a phenomenon that has changed the way we experience and conduct so many aspects of life.

The world's first national public television service—its first high-definition service of programs to be delivered on a published schedule—was beamed from British Broadcasting Company (BBC) studios in London, on 2 November 1936. After the BBC correspondent Elizabeth Crowell (BBC 2007) announced, “This is direct television from Alexandra Palace,” (the now-famous landmark where the studios were located), an entertainer sang the following ditty:

The air has eyes that scan us from the skies
And ears that listen from the blue . . .
So you needn't roam
From your own happy home,
The world will pass you in review.

Television was one of the nineteenth century's confident predictions about technology in the twentieth, but it took decades of the new century to reach fruition and only in the second half did it become a global phenomenon. Television transformed political life when it arrived; a new “consumer” economy driven by the all-pervading cultural influences of the West came to depend upon it. The world indeed “passed in review,” but television led to a kind of secondary environment of images in which we all now live.

In the twenty-first century television is undergoing a technological and institutional transmutation. Between the 1950s and 1990s television was organized as a regulated and essentially national medium dependent on the scarce resource of electromagnetic frequencies. At the end of the era it was a medium of abundance, with hundreds of satellite, cable, and digital channels available in every home. These new sources of images, passing through new technologies and produced by a new generation of inexpensive miniaturized equipment, emerge from jurisdictions outside the receiving countries. Television once provided the essence of a nationally authorized culture; now it is inextricably part of an international industry, increasingly beyond the control of governments.

Television's inventors, from the 1890s until the 1950s, thought of the medium as an alternative to radio, theater, or cinema—a new way of delivering information and entertainment—but they had little idea of television capacity to reach beyond those functions. What the inventors couldn't anticipate was that television would become *normative*, that so much of what we view would contrive to suggest how things ought or ought not to be. Television has come to delineate

for us the boundaries of transgression; beneath the most routine or trivial entertainment the medium operates as subtle instructor. It offers a continuous flow of experiences from which we have come to draw much of the substance of our identities.

Many have tried (although none have yet succeeded) in distilling the essence and nature of nature of television's influence, but there's no doubt television has changed and altered us. Almost since its inception television has spawned controversy. It may be difficult to trace the ideological influence of a single program but no one denies that television amplifies the processes of change in fashion and ideas, sometimes sparking political uproar. Our most influential images of authority derive from television; it is where we register at various levels of our minds the personae of heads of state, sporting heroes, and celebrities. To use the phrase commonly employed by sociologists, television "sets the agenda."

Television Technologies

Television can be traced to the scientists and engineers from all over the world who tried to send visual images over long distances. In 1873, the British telegraph engineer Joseph May introduced his discovery of selenium rods capable of converting light into an electric signal. Many engineers who dreamed of transmitting moving images welcomed this knowledge, because the photosensitivity of selenium rods meant the possibility of a "picture telegraph."

The scanning disk, proposed by the German inventor Paul Nipkow in 1884, moved the dream a step closer. Although he never built it, Nipkow conceptualized a mechanical television employing two synchronically rotating disks, each with twenty-four holes. (See figure 1.) Once light was projected onto the outer rim of one scanning disk, the light would pass the holes one by one. A selenium cell situated behind the disk generated electric signals and the signal would reconstruct the original image by passing through the other rotating disk. As the rotating disks projected a sequence of signals, the disks would transfer a complete image.

The operation of Nipkow's disks for mechanic television. J. van den Ende, W. Ravestejin, & D. de Wit. (Winter 1997–1998). Shaping the early development of television. *Technology and Society Magazine* 16(4).

Charles Francis Jenkins, the U.S. inventor of the first motion picture projector in 1895, demonstrated to the public the first transmission of a moving silhouette by wireless in 1922. Two years later, John Logie Baird, an engineer from Scotland, was the first to publicly demonstrate a mechanical television capable of transmitting halftone images. Jenkins was granted the first experimental television license from the U.S. Federal Radio Commission in 1927 and began broadcasting simple cartoon programs in 1928. Baird also received permission from the British Post Office to broadcast a short program three times a week with the BBC.

Competition between the Russian-born Vladimir Kosma Zworykin, who applied for a patent in 1923, and the U.S. inventor Philo Taylor Farnsworth, who presented first workable electronic television in 1927, spurred the development of electronic television. Farnsworth's system employed a cathode ray tube, a vacuum tube coated with a phosphorescent material. A cathode ray could move at the speed of light, which solved the flickers from rotating disks. In 1934 Farnsworth developed an all-electronic television employing his image dissector tube at 250 lines per picture and 25 frames in collaboration with Baird

Television is a medium of entertainment which permits millions of people to listen to the same joke at the same time, and yet remain lonesome. • **T. S. Eliot (1888–1965)**

Television Ltd. Meanwhile, Zworykin proposed the iconoscope in 1929, which influenced Electronic and Musical Industries Ltd. (EMI) to build an improved iconoscope tube in 1934.

While the London Television Service sold over 500 televisions a week, the Radio Corporation of America (RCA) and the National Broadcasting Company (NBC) in the U.S. suffered from sluggish sales, largely because of poor resolution. Furthermore, multiple manufacturers in the United States adhered to incompatible standards and the number of available programs was small. In order to set a national standard, the National Television System Committee (NTSC) was formed in 1940 and the next year the Federal Communications Commission (FCC) approved a new 525-line NTSC system as a national television standard. Thanks to improved standards, the industry turned a corner.

The Columbia Broadcasting System (CBS) demonstrated the first color television soon after World War II. This enabled CBS to gain approval of color broadcasting from FCC in 1950. In 1951, RCA and NBC introduced a system capable of complete color broadcasting that was compatible with existing monotone televisions. NBC successfully transmitted the first coast-to-coast color broadcast in 1953. The new system was approved by the NTSC in 1952, forming the basis for all analog televisions in the United States. Canada, several Asian countries, and several Latin American countries adopted the U.S. standards.

Meanwhile, Europe made available two different standards of color television. In 1956, the French inventor Henri de France developed a 625-line standard, ensuring higher resolution than the U.S. system. Germany also employed a 625-line standard adopted by the BBC in 1964. Most European countries (excluding France), several Latin American countries, Australia, the Middle East, China, and several other Asian countries adopted the German system.

Cable television began in 1949 in the United States. The original use of cable was to serve communities with poor over-the-air signals reception. Cable TV adopted a redistribution system with a large community antenna connected by cable to individual

homes. Fiber optics superseded coaxial cable, providing less interference and greater capacity. As capacity increased and cable systems digitalized, cable was capable of handling huge data with high bitrates such as high-speed Internet, telephony (including voice and fax), and on-demand video.

Cable television produced a noticeable impact on the television business model. Using a wire and a set-top box, cable operators can control their service to reach designated subscribers and can provide various television channel tiers with different subscribers at different rates. After the early 1970s when the first pay television network, Home Box Office (HBO), emerged in the United States, the subscription-based revenue model (or pay TV) gained popularity.

Satellite television delivers broadcast signals via satellite. The first commercial communications satellite, nicknamed Early Bird, was launched by the International Telecommunications Satellite Organization (Intelsat) in 1965. HBO began using satellite to deliver its own signal to cable systems in 1976. The first direct broadcasting service, British Sky Television (BSkyB) was opened in 1989 as a free analog service. Two years later, BSkyB launched a subscription-based digital satellite service named Sky Digital. The emergence of satellite television poses a challenge to nation-based regulation systems. Satellite transmissions generated by one country can be received in neighboring countries, posing dilemmas such as programming from one country that threatens the national identity and cultural independence of another.

Digital television is an emerging technology with superior signal transmission. The advantage of digital over analog is to ensure optimal and efficient utilization of spectrum. Digital technology in television systems enables the broadcast of high-definition television (HDTV) and improved sound, the multicast of multiple programs over a single channel, and data communication for interactive web services. Most governments have firm plans of digital conversion for terrestrial televisions.

Digitalization promotes competition in the market in two ways. First, digitalization allows more channels transmitting over limited radio-waves. Second,

Technology has changed the look of the television set (this photo was taken in the 1950s) and the family dynamic as well. Library of Congress.

digitalization of communications infrastructure blurs the border between telecommunication and broadcasting because digital format can be conveyed to any type of digital communication infrastructure, such as mobile phones. Digitalization therefore enables any communication service provider to enter the broadcasting market. Mobile television has become a reality. Thanks to the increasing penetration rate of mobile devices, mobile TV is increasing in popularity.

Television Around the World

Since the first television was introduced to the public, television sets have become ubiquitous in homes, evolving from a novelty to a necessity. Television penetrates over 90 percent of households in the developed world; 99 percent of U.S. households have at least one television set. Viewing time continues to increase. The annual averages of television viewing times per day per household in the United States have steadily increased from 5 hours and 56 minutes in 1970 to 8 hours and 14 minutes in 2006.

As a leading force, U.S. television came to dominate the international market for programs and thus enter deeply into the consciousness of distant societies. In contrast, under the Soviet Union, for decades a

totalitarian system used the medium to sustain itself in power but also undermined itself with the resulting combination of distastes and ennui. But now, in Russia and its former satellites the medium of television may grow into new program industries. Similarly, in China television is growing very rapidly but has yet to exercise a significant influence outside the nation's own borders. The television of Brazil, by comparison, has proven to be a great world influence, but in 1980 it was little known outside a few countries of South America.

The new myth-making of the twenty-first century is as likely to emanate from Russia, Japan, China, or South America as from the United States. There are industrial and investment issues to be resolved but as the medium becomes abundant thanks to inexpensive technology, other more historically rooted factors will come to influence the flows of the marketplace.

Producing and Consuming Television

Between roughly 1940 and 1970, television was a closed and somewhat mysterious medium. Programs were created by small groups of professionals and the public enjoyed access only as passive viewers. Today children learn to use video as a means of self-

expression. In some countries there are neighborhood channels available for almost anyone to use. The great chasm between viewers and producers has in large part dissipated.

“Radio and more especially, television have . . . become the prime instruments for the management of consumer demand . . . The industrial system is profoundly dependent on commercial television and could not exist in its present form without it.” So wrote the economist John Kenneth Galbraith in *The New Industrial State* in 1967. By the 1990s television was ever more dependent on advertising revenue. The launch of mass consumer products has become ever more dependent upon access to television and so in looking at the evolution of this medium one is looking at an unexpected prop for the wider economic system. That provides a further constraint on the culture of the medium and as the audience fragments—and as the larger *social* experience of television disappears—the pressures upon programs to perform economic work grow more severe.

For the first half-century of television the biggest issue was that of the relative legitimacy of public and private control of the medium. Indeed, radio and television together constituted a major battlefield in the fight between three distinct broadcasting “ideologies”: competitive commercial service, license-fee-funded public service, and a mixed policy. The argument has raged for decades as to which most encourages native talent, most strengthens or weakens the medium in the face of government, and is most conducive to the creation of a diversity of programming. The argument has never been won but the new technological opportunities suggest that nowhere can the traditional public broadcasting institutions continue to hold a monopoly. They are destined to face an array of commercial rivals.

In the long run how will television be judged? Some believe the medium has short-changed human society while holding its attention, consuming much energy while ignoring the fundamentals of life. Television has, they insist, touched the audience at the most superficial levels but without seeming to accept responsibility for its own consequences. Others disagree,

saying that television has merely reflected society and should not be blamed for what it has merely observed. But has the medium held a mirror before the object of its gaze or, rather, operated a gigantic reflecting (or deflecting) device, with built-in tendencies to distort? It has made us see but has it made us look deeply? It may have aided the disruption of cultures, but it has helped much in the overthrow of tyrannies. It has wantonly manipulated our wants and distorted our true needs, but it has democratized and leveled, opening the eyes of millions to things of which they had long been deprived. It has reflected ugliness in our world but taught hygiene and brought literacy to rural and urban poor alike.

The professionals of television—celebrities—have become a new kind of priesthood, mediating between events and audiences. As with other priesthoods their power can be exaggerated and perhaps they have encouraged that exaggeration. But as the medium proliferates, cheapens, deregulates, and multiplies the numbers of those who control its message, there could well be a turning point, a global reassessment, leading to major change in the shape of a reaction against the sheer ubiquity and overweening power of the medium.

Terrorism

Terrorism is an organized campaign of violence intended to frighten a particular population, often to further a religious, political, or social cause. Incidents of terrorism are evident throughout recorded history, reaching new levels of intensity in the Middle East after the creation of Israel in 1948, and culminating in the September 11 attacks in the United States in 2001.

The word *terrorism* refers to organized acts of violence intended to frighten others and revenge past, or perceived, injustices suffered by the terrorists or their supporters. Attacks upon a hated rival or unjust ruler are age-old, but such acts become terrorism only when the individual who performs the act does so with the support of fellow sufferers who hope their cause will benefit from the fear terrorism provokes.

The oldest recorded instance of terrorism may be found in the Bible where the books of Samuel and Chronicles refer to wandering companies of prophets who worshipped Yahweh and became the core of the army Saul led against the Philistines and other enemies (1 Samuel 10:26). They fought for Yahweh and the religion of the desert, then being challenged by worship of baals—agricultural deities already established in the land of Canaan. The prophets of Yahweh eventually prevailed, supported from time to time by terroristic acts against enemies like the Amalekites, whom Saul utterly destroyed (1 Samuel 15:20).

In ancient Greece, Harmodius and Aristogeiton, who assassinated the tyrant Hipparchus of Athens in 514 BCE, were later regarded as defenders of liberty and honored with statues, but their motives were probably merely personal. In Rome, the assassination

of Julius Caesar in 44 BCE was justified at the time as a defense of the republican form of government. Augustus, as Caesar's heir, tried to suppress that interpretation of his adopted father's death, but the historian Tacitus makes clear that it lingered among the Roman senators nonetheless.

The Assassins

In other times and places innumerable kings and chieftains were killed by those around them, but when personal fear or hatred was the motive, historians do not consider such murders as acts of terrorism. The first unambiguous example of a prolonged and secret terrorist campaign centered in Iran and Syria among a small number of Shi'a Muslims who rejected the legitimacy of Seljuk Turkish rulers, pinning their hopes on a hidden imam they believed was the sole legitimate ruler. In 1090, the sect seized a mountain fortress in Iran that became their headquarters for planning surprise assassinations of local emirs. It remained in their hands until 1256 when the Mongols captured the fortress and massacred all its inhabitants. The sect enjoyed widespread initial support, but after its leaders persuaded zealous youths to sacrifice their own lives by killing local rulers in the most public and dramatic fashion possible, sentiment eventually turned against them. Popular rumor eventually held that the assassins were inspired by smoking hashish, not by religious faith and hope; Christian crusaders later learned to call the sect "Assassins"—a name derived from the Arabic word for hashish. But, for more than a century and a half, the sect survived and secretly dispatched assassins to kill its enemies—sometimes planting an agent

in court years in advance. Consequently, religious terrorism became a reality throughout much of Iran and Syria. Scores of local rulers died of stab wounds inflicted by devotees of the sect, and suicidal killing entered the Islamic tradition to the dismay of almost all constituted authorities.

Religion and Politics

Other religious and political causes subsequently provoked outbursts of directed violence. Throughout the middle ages, the commercial and money lending roles that Jews played in Christian lands created tension between the two communities that sometimes boiled over into violence resembling terrorism. But for all the thousands killed in such outbursts, rulers' need for loans always restored a modicum of peace and order. Heretics, too, like the Cathari of southern France, were objects of attacks and extinctions. Buddhist sects played a similar rebellious role in China and Japan as recently as the eighteenth century, and Hindu sects did not always remain peaceable either. But none of these religious frictions achieved the organized, ongoing character of the Assassins' targeted murders of the high and mighty, aimed at inspiring fear and changing public attitudes.

A closer approximation arose in western Europe after the Reformation when rival Catholic-Protestant movements bred innumerable plots for assassinating rulers. For example, a Catholic assassin shot William the Silent of the Netherlands in 1584 in an age when pistols made killing at a distance much easier than before, while the rivalry between Elizabeth I of England and Mary Queen of Scots generated rival assassination plots (and led to Mary's execution in 1587) across a generation of religious persecution and uncertainty.

More recently, Christian-Muslim frictions played a principal role in nationalist risings within the Ottoman Empire, beginning as early as 1768, and becoming partially successful in Serbia after 1803 and in Greece after 1821, thanks to foreign support from Russia and Western powers. Both sides resorted to terroristic tactics. When Armenians failed to gain effective international support for their national independence at the end of the century, a handful of terrorists launched attacks against Turks. Then, during World War I, the Turkish government decided to drive millions of Armenians from their homelands and inaugurated a massacre of those who failed to escape into Russia. The Armenian massacres of 1916–1918 still remain an acute issue between the two nations.

During the nineteenth century, religious differences ceased to command primary loyalties in Europe, but secular causes soon arose to foment terrorism. Frustrated nationalists, anarchists, and socialists pursued their goals by assassinating officials and rulers or provoking other kinds of violence. Successful terrorist campaigns, like that which preceded the emergence of the state of Israel in 1948, are seldom officially celebrated since established governments fear such attacks. Unsuccessful campaigns last longer and, even when they eventually fade away, may leave heroic memories behind.

Northern Ireland

When the Irish Free State was created in 1920, leaving Northern Ireland (Ulster) subject to the British crown, an angry remnant formed an illegal organization, the Irish Republican Army (IRA), to fight on for a united Ireland. Though it was militarily defeated and its ability to occupy territory ended in 1922, for more than eighty years it organized terrorist campaigns against the British in Great Britain as well as in Northern Ireland, relying mainly on targeted assassinations and bombs timed to explode after those who planted them were safely out of the way. Eventually the anger sustaining the IRA campaign dwindled until its leaders negotiated a stable cease-fire agreement with the two main Unionist parties in 1998. In 2002, Unionists suspended a power-sharing agreement, implemented in 1999, when an IRA spy ring within the Sinn Fein party was discovered. The peace agreement was not renegotiated until 2005, when IRA handed over its arms and formally decommissioned itself. The extreme Democratic Unionist Party (DUP) has remained distrustful that the IRA has irrevocably renounced violence, and a small die-hard faction in Northern Ireland calling itself the “real IRA” has occasionally continued to detonate bombs and kill police officers. Cooperation between all political parties has continued, however, and in May 2007 a governing system in which Unionists and Sinn Fein leaders share power and rule Ireland, while remaining a part of Great Britain, was finally

achieved, and has survived, though precariously, through 2009.

Basque nationalists in Spain and France initiated a similar terrorist campaign for full independence in 1959. Their organization still persists but in recent years fewer bombs have exploded and Basque terrorism may be winding down. Elsewhere in the world, the post-World War II disruption of European empires in Asia and Africa was often hastened by acts of terrorism, and when the colonial rulers tried to hang on, as happened in Algeria and Vietnam, for example, bitter, full-scale wars ensued, featuring acts of terrorism on both sides. Nor have post-colonial Africa, Asia, and Latin America escaped terrorist violence within state borders and across them. In 1994, ethnic strife provoked an outburst of wholesale terrorism in Rwanda, and similar violent clashes are still common in Sudan and Congo, while twenty-six years of terrorist struggle may have ended in Sri Lanka with the surrender of Tamil fighters in 2009. In the Americas, both Colombia and Mexico still suffer from terrorism organized by drug traffickers exporting cocaine and other drugs to the United States.

As long as populations of different languages and customs find themselves living under the same government, nationalist movements are liable to provoke terrorism. As large-scale migration adds new strands to the ethnic mix in the world’s big cities, urban struggles among ethnic groups may become far more violent than when voluntary allegiance to a common national identity was taken for granted.

Social Reform

Anarchist and socialist programs for social reform provided the other principal inspiration for terrorism in the nineteenth and twentieth centuries. Modern anarchism arose from the writings of Pierre-Joseph Proudhon, who coined the term in 1840. It was turned into a movement by Mikhail Bakunin (1814–1876), whose effort to dismantle governmental and other forms of authority attracted considerable support among working men in Italy and Spain. Bakunin advocated violence, and between 1894 and

Everybody's worried about stopping terrorism. Well, there's a really easy way: stop participating in it. • **Noam Chomsky (b. 1928)**

1914 anarchists succeeded in killing a notable array of prominent persons, including the president of France, the king of Italy, and U.S. president William McKinley. But anarchism disintegrated as an organized movement during World War I.

Russian revolutionaries, calling themselves the People's Will, launched a similar outburst of political assassinations in 1878. After killing several high police officials, their success climaxed in 1881 when, after several failed attempts, a member of the organization threw a bomb that killed both himself and Czar Alexander II. Arrests and the executions of suspected revolutionaries ensued. But popular discontent became manifest in 1905, when defeat by the Japanese in the Far East discredited the Russian government, and twelve years later heavy casualties in World War I led to a successful Communist revolution in 1917.

State-Sponsored Terrorism

Despite the freedom and equality that Marxists expected to arise spontaneously when the new government abolished private property, terrorism did not disappear from Communist Russia. It became especially acute when party morale was strained in 1937–1938 by the forced establishment of collective farms and a strenuous campaign to build electric power plants and modern factories. Leading Communists were put on trial and compelled to confess to treason before suffering execution, and many army officers, suspected of disloyalty, were summarily killed as well. No one could be sure a secret denunciation might not provoke sudden death or imprisonment, and, ironically, a chief of the Russian secret police was among those arrested and killed.

Though thousands of innocent persons died, and millions were sent to forced labor camps in Siberia, the terror was successful in the sense that public dissent disappeared, and new jobs created by manufacturing tractors, trucks, and modern armaments won over most of those conscripted for work in the new factories. In 1949, when Communists came to power in China, similar policies were sustained by

comparable terror, especially during the Great Leap Forward of 1958–1960. After taking power in 1975, Marxists in Cambodia went even further by compelling nearly all urban dwellers to endure forced labor in the countryside where about a million died.

Marxists nonetheless viewed official terrorism as a regrettable expedient for suppressing temporary and misguided opposition. That was not true of Hitler and his Nazi followers, whose anti-Semitism inspired the only sustained, bureaucratic, and deliberate effort ever launched to exterminate a whole population. The Nazis kept their plan secret while they transported more than 5 million European Jews and a few other “undesirables” away from their homes and delivered them to death in poison gas chambers between 1943 and 1945. The scale and cold-bloodedness of this slaughter is unmatched, yet, it could be argued that the Holocaust was not terrorism, since it was not primarily intended to frighten Jews or change their ways.

Religious, or ostensibly religious, quarrels assumed a new intensity after the establishment of the Jewish State of Israel in 1948. Millions of Palestinian Arabs were driven from their homes by victorious Jewish armies and long aspire to return some day when Arab armies might come to their aid and destroy the new state. A series of short wars did ensue, and, until very recently, the Israelis were easily victorious.

September 11

On September 11, 2001, Islamic terrorists hijacked four commercial airplanes. Two planes taking off from Boston were flown into the “twin towers” of the World Trade Center in New York City, destroying them; a third, which departed from Dulles International Airport, hit the Pentagon in Washington, D.C., causing extensive damage; the fourth, flying from Newark, New Jersey, probably heading for the White House, crashed in a field in Shanksville, Pennsylvania, as passengers attempted to recapture the airliner from the hijackers who had overtaken the cockpit. The September 11 attacks, the single most successful incident of terrorism in modern history, resulted in the deaths of 2,973 civilians, plus 19 hijackers.

The outrage and fear this incident aroused among Americans is hard to exaggerate. The thousands of deaths, combined with the visceral images of the twin towers burning and collapsing on the nation's TV screens, made indelible impressions. The attack was planned and carried out by a formerly obscure organization, al-Qaeda, headed by a wealthy Saudi native named Osama bin Laden. At the time of the attacks, he was operating in Afghanistan, a guest of Taliban fighters who had recently taken control of the country, where they started to enforce their own extreme version of Islamic law and conduct.

The War on Terror

President George W. Bush (in office 2001–2009) responded by declaring a “War on Terror,” and within months sent U.S. soldiers to Afghanistan where they soon defeated the Taliban but failed to catch bin Laden, who is believed to have fled to the mountainous tribal region between Afghanistan and Pakistan. The War on Terror strained established patterns of American law and justice as the government imprisoned hundreds of suspects for years without formal trial, calling them “enemy combatants,” while authorizing controversial methods of interrogation many labeled torture.

This tangle has yet to be resolved by President Barack Obama. The United States also keeps armies in Afghanistan and in Iraq, where the Bush administration decided to overthrow the existing government on what turned out to be faulty information about weapons of mass destruction. On top of all that, the Taliban have returned to parts of Afghanistan; the U.S.-sponsored governments in Iraq and Afghanistan are dubiously secure, and al-Qaeda continues to operate in the border region between Afghanistan and Pakistan.

So the War on Terror continues with no end in sight. In view of all the grievances that incite acts of terrorism—suicide bombings are the latest and most

feared tactic—winning is inherently impossible, if winning means ending such acts. Instead, more acts of terrorism crop up in almost every country of the world. That is not surprising. Terrorism has existed for millennia; and the fourfold multiplication of human numbers across the past century guarantees that innumerable persons suffer frustration today and are tempted to resort to terrorism tomorrow, being ready, even eager, to end unhappy lives with acts of angry defiance.

Textiles, the broad term used to encompass the range of material objects created from fiber, cord, fabric and/or string—and manipulated by weaving, tying, sewing, knitting, braiding, and other techniques—have been a part of human culture since prehistoric times. Textiles can be studied to examine not only a peoples’ aesthetic sense and development, but to provide insight about socioeconomic, political, and cultural aspects of their lives.
